Abstract

This papers extends the Nuprl proof assistant (a system representative of the class of extensional type theories à la Martin-Löf) with *named exceptions* and *handlers*, as well as a nominal *fresh* operator. Using these new features, we prove a version of Brouwer's Continuity Principle for numbers. We also provide a simpler proof of a weaker version of this principle that only uses diverging terms. We prove these two principles in Nuprl's meta-theory using our formalization of Nuprl in Coq and show how we can reflect these meta-theoretical results in the Nuprl theory as derivation rules. We also show that these additions preserve Nuprl's key meta-theoretical properties, in particular consistency and the congruence of Howe's computational equivalence relation. Using continuity and the fan theorem we prove important results of Intuitionistic Mathematics: Brouwer's continuity theorem and bar induction on monotone bars.

Categories and Subject Descriptors D.3.1 [*PROGRAMMING LANGUAGES*]: Formal Definitions and Theory; F.4.1 [*MATHEMATICAL LOGIC AND FORMAL LANGUAGES*]: Mathematical Logic

Keywords Intuitionistic Type Theory, Nuprl, Coq, Continuity, Nominal Type Theory, Exceptions, Squashing, Truncation

1. Introduction

Continuity. There are two principles that distinguish Brouwer's mathematics from other constructive mathematics, namely *bar induction* and a *continuity principle* [13, 21, 40, 58, 84, 91, 92, 94, 95]. In this document we consider the following weak and strong continuity principles on the Baire space $\mathcal{B} = \mathbb{N}^{\mathbb{N}} = \mathbb{N} \to \mathbb{N}$ ($\mathbf{\Pi}$,$\mathbf{\Sigma}$ are the logical $\forall$,$\exists$; as explained below, $\underline{\mathbf{\Sigma}}$ is a truncated/squashed existential quantifier; $+$ in the context of types is the disjoint union type; `inl` is the left injection constructor; `isl` checks whether a term is a left injection; $\mathbb{N}_n$ is the type of natural numbers strictly less than n; and $t =_T u$ expresses that t and u are equal in type T):

$$\begin{array}{l}\texttt{WCP} = \mathbf{\Pi}F{:}\mathcal{B} \to \mathbb{N}.\\ \quad\quad \mathbf{\Pi}f{:}\mathcal{B}.\\ \quad\quad\quad \underline{\mathbf{\Sigma}}n{:}\mathbb{N}.\ \mathbf{\Pi}g{:}\mathcal{B}.f =_{\mathbb{N}^{\mathbb{N}_n}} g \to F(f) =_{\mathbb{N}} F(g)\end{array}$$

$$\begin{array}{l}\texttt{SCP} = \mathbf{\Pi}F{:}\mathcal{B} \to \mathbb{N}.\\ \quad\quad \underline{\mathbf{\Sigma}}M{:}(\mathbf{\Pi}n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to (\mathbb{N}{+}\texttt{Unit})).\\ \quad\quad\quad \mathbf{\Pi}f{:}\mathcal{B}.\\ \quad\quad\quad\quad \underline{\mathbf{\Sigma}}n{:}\mathbb{N}.\\ \quad\quad\quad\quad\quad\quad M\ n\ f =_{\mathbb{N}+\texttt{Unit}} \texttt{inl}(F(f))\\ \quad\quad\quad\quad\quad\quad \wedge\ \mathbf{\Pi}m{:}\mathbb{N}.\texttt{isl}(M\ m\ f) \to m =_{\mathbb{N}} n\end{array}$$

`WCP` is the usual *pointwise continuity principle* on natural numbers, sometimes called *weak continuity principle*. It says that given a function F of type $\mathcal{B} \to \mathbb{N}$ and a function f of type $\mathcal{B}$, $F(f)$ can only depend on an initial segment of f. The length of the smallest such segment is called the *modulus of continuity* of F at f. Kleene used some version of the *strong continuity principle* `SCP`[1] to prove bar induction on monotone bars from bar induction on decidable bars [58, pp.78]. `SCP` says that there is a uniform way (called M in the formula) to decide whether n is the modulus of continuity of F at f, and if so returns the value $F(f)$ [58, pp.70–71].

Truncation/Squashing. Escardó and Xu [45] proved in Agda [3, 19] that `WCP` is false when $\underline{\mathbf{\Sigma}}$ is the sum type $\mathbf{\Sigma}$ of Martin-Löf's type theory. They also mention that this principle is consistent when $\mathbf{\Sigma}$ is *truncated at the propositional level* [93, pp.117]. In Nuprl [7, 28], propositional truncation corresponds to *squashing* a type down to a single equivalence class (i.e., all inhabitants are equal) using quotient types [30]: $\lfloor T = T//\texttt{True}$. $\lfloor T$ is a proof-irrelevant type. Its members are the members of T, and they are all equal to each other because if $x, y \in T$ then $(x =_T y \iff \texttt{True})$. In Nuprl we often squash types in a much stronger sense by throwing away the evidence that a type is inhabited and squashing it down to a single inhabitant using, e.g., set types: $\downarrow T = \{\texttt{Unit} \mid T\}$ (this is the same definition as in [28, pp.60]). The only member of this type is $\star$[2], which is the single inhabitant of `Unit`, and $\star$ inhabits $\downarrow T$ if T is true/inhabited, but we do not keep the proof that it is true. Note that $\lfloor T \to \downarrow T$ is true because it is inhabited by $\lambda x.\star$, but we cannot prove the converse because to prove $\lfloor T$ we have to exhibit an inhabitant of T, which $\downarrow T$ does not give us because we have thrown away the evidence that T is inhabited (only $\star$ inhabits $\downarrow T$). Appendix F presents derivable inference rules that one can use to reason about these two squashing operators.

In this paper we prove that versions of `WCP` and `SCP` are true facts about Nuprl's functions. We carry out these proofs in Nuprl's meta-theory [5, 6] using our formalization of Nuprl in Coq [15, 36], which contains among other things: (1) an implementation

[1] Rathjen calls it "Strong Continuity for Numbers" [84] and names it C-N (as in [92]). Dummett refers to it as "a stronger version of the Continuity Principle", names it $\text{CP}_{\exists n}$, and later calls it "the Continuity Principle" [40, pp.59–60]. Troelstra [91, pp.1006] calls it CONT_0. This is Kleene's *27.2 principle [58, pp.73], which he calls "Brouwer's principle (for numbers)". Bridges and Richman [21, pp.119] mention that `SCP` is equivalent to a "principle of continuous choice", which they divide into a continuous part, namely `WCP`, and a choice part, namely the axiom of choice $\text{AC}_{1,0}$ (see Sec 5.3). Note that $\text{AC}_{1,0}$ is also sometimes used to refer to `SCP` [48, 96].

[2] The term $\star$ can be thought of as `()` in, e.g., OCaml, Haskell or SML.

of Nuprl's computation system; (2) an implementation of Howe's computational equivalence relation [54] and a proof that it is a congruence; (3) a definition of Nuprl's *Constructive Type Theory* (CTT), where types are defined as *Partial Equivalence Relations* (PERs) on closed terms following Allen's PER semantics [5, 6]; (4) definitions of Nuprl's derivation rules and proofs that these rules are valid w.r.t. Allen's PER semantics; (5) and a proof of Nuprl's consistency [9, 10].

In Sec. 3 we prove WCP where $\underline{\mathbf{\Sigma}}x{:}T.\ P$ is defined as $\downarrow\mathbf{\Sigma}x{:}T.P$, and refer to this principle as $\text{WCP}_{\downarrow}$. We call $\text{WCP}_{\downarrow}$ the version of WCP where $\underline{\mathbf{\Sigma}}$ is $\downarrow\mathbf{\Sigma}$. In Sec. 4 we prove SCP where the first (outer) $\underline{\mathbf{\Sigma}}$ is $\downarrow\mathbf{\Sigma}$ and the second (inner) is $\downarrow\mathbf{\Sigma}$, and refer to this principle as $\text{SCP}_{\downarrow}$. There proofs are carried out using our Coq formalization of Nuprl. We make these results available in Nuprl as inference rules, and show how we can derive directly in Nuprl a proof of $\text{SCP}_{\downarrow}$ without the second (inner) squashing operator. Sec. 5 shows that $\text{SCP}_{\downarrow}$ and $\text{WCP}_{\downarrow}$ are equivalent. Even though the implication $\text{WCP}_{\downarrow} \rightarrow \text{WCP}_{\downarrow}$ is trivial, we believe our proof of $\text{WCP}_{\downarrow}$ in Sec. 3 is still valuable because of its simplicity and because $\downarrow$ is often enough.

An important point is that we add operations sufficient to prove these principles to the Nuprl proof assistant without breaking any property of its type theory such as Nuprl's consistency or the congruence of Howe's computational equivalence relation.

Effectful computations. Following Longley's method [66], we use computational effects [12], namely named exceptions, to derive $\text{SCP}_{\downarrow}$. The basic method to find the n such that $F(f)$ depends only on the first n elements of f is a program $P(F, f)$ that works as follows: P tests whether F applies its argument f to a number n by running the sub-routine (written in an ML-like language):

```
let exception e in
(F (fun x => if x < n then f x else raise e);
 true) handle e => false
```

Then by testing F on increasingly larger n's, if the continuity principle is true, P eventually finds an n such that the test returns `true`[3]. However, for extensionally equal F and G, $P(F, f)$ and $P(G, f)$ could return different numbers. For example, if $P(F, f) = m$ and G is constructed from F by replacing an expression t occurring in F with $(\texttt{let \_} := f(m+1) \texttt{ in } t)$, that first evaluates $f(m+1)$ and then evaluates t, then $P(G, f)$ is not guaranteed to be m. This is why we only realize squashed versions of the above mentioned continuity principles.

As Longley mentions, if F can catch the exception e then $P(F, f)$ will not necessarily compute F's modulus of continuity at f. Therefore, we have extended Nuprl with exception handlers that can only catch exceptions with a specific name, and we have added the ability to generate fresh names (Sec. 7 discusses related nominal systems).

Related proofs of continuity. This is not the first (formal) proof that a type theory satisfies Brouwer's continuity principle. Coquand and Jaber [33, 34] proved the *uniform* continuity of a Martin-Löf-like intensional type theory using *forcing* [11, 13, 26, 27, 71]. Their method consists in adding a generic element `f` as a constant to the language that stands for a Cohen real of type $2^{\mathbb{N}}$, and defining the forcing conditions as approximations of `f`, i.e., finite sub-graphs of `f`. They then define a suitable *computability* predicate that expresses when a term is a computable term of some type up to approximations given by the forcing conditions. The key steps are to (1) first prove that `f` is computable and then (2) prove that well-typed terms are computable, from which they derive uniform continuity (the uniform modulus of continuity is given by the approximations). The uniform continuity principle is, where F is now a function on the Cantor space $\mathcal{C} = 2^{\mathbb{N}}$ instead of the Baire space: $\text{UCP} = \mathbf{\Pi}F{:}\mathcal{C} \rightarrow \mathbb{N}.\underline{\mathbf{\Sigma}}n{:}\mathbb{N}.\ \mathbf{\Pi}f, g{:}\mathcal{C}.f =_{2^{\mathbb{N}_n}} g \rightarrow F(f) =_{\mathbb{N}} F(g)$. Escardó and Xu [45] showed that in the case of uniform continuity $\underline{\mathbf{\Sigma}}$ can equivalently be $\mathbf{\Sigma}$ or $\downarrow\mathbf{\Sigma}$. In [34], Coquand and Jaber provide a Haskell realizer that computes the uniform modulus of continuity of a functional on the Cantor space[4].

Similarly, Escardó and Xu [99] proved that the definable functionals of Gödel's system T [49] are uniformly continuous on the Cantor space (without assuming classical logic or the Fan Theorem). For that, they developed a constructive continuous model, the C-**Space** category, of Gödel's system T, and proved that C-**Space** has a *Fan functional* that given a function F in $\mathcal{C} \rightarrow \mathbb{N}$ can compute the modulus of uniform continuity of F. Relating C-**Space** and the standard set-theoretical model of system T, they show that all T-definable functions on the Cantor space are uniformly continuous. Finally, using this model, they show how to extract computational content from proofs in HA^{ω} extended with a uniform continuity axiom UC, which is realized by the Fan functional.

In [44] Escardó provides a simple and elegant proof that all T-definable functions are continuous on the Baire space and uniformly continuous on the Cantor space using a *generic element* as in [33] but without using forcing. His method consists in providing an alternative interpretation of system T, where a number is interpreted by a dialogue tree that "describes the computation of a natural number relative to an unspecified oracle $\alpha : \mathbb{N}^{\mathbb{N}}$" [44]. Such a computation is called a *dialogue*, which is a function that given a dialogue tree, returns a function of type $\mathcal{B} \rightarrow \mathbb{N}$. Escardó first proves that dialogues are continuous. This means that a function is continuous if it is extensionally equal to a dialogue. The key steps are to (1) define a suitable logical relation between the standard interpretation and the alternative one that relates numbers and dialogues w.r.t. a given oracle; and (2) prove that all system T terms are related under the two interpretations. It then follows that for all system T term t of type $(\iota \Rightarrow \iota) \Rightarrow \iota$ (where ι is the type of numbers), there is a dialogue tree d such that the standard interpretation of t and the dialogue on d are extensionally equal functions, from which he derives uniform continuity. The dialogue d is built using a *generic* sequence that allows dialogue trees to call the oracle.

Results. Our proof method differs from the ones discussed above in the sense that it is "mostly" computational. In Sec. 3 we use diverging terms to prove $\text{WCP}_{\downarrow}$, and in Sec. 4 we use computational effects (named exceptions) to probe terms and derive $\text{SCP}_{\downarrow}$ using (non-strict) lock-step simulations of these effectful computations. Sec. 5 shows that $\text{SCP}_{\downarrow}$ and $\text{WCP}_{\downarrow}$ are equivalent. To prove $\text{SCP}_{\downarrow}$, we added named exceptions as well as a *fresh* operator to Nuprl's computation system, and showed that these additions preserve Nuprl's key meta-theoretical properties, such as consistency (see Sec. 2.3 and 4.3) and the congruence of Howe's computational equivalence relation (see Sec. 2.2 and 4.2). As mentioned in Sec. 4.9, $\text{SCP}_{\downarrow}$ justifies a corresponding inference rule that we added to Nuprl. Sec. 5 discusses the relation between WCP and SCP and the connection with the axiom of choice, as well as the status of the (squashed) axiom of choice in Nuprl. Using those continuity rules, as explained in Sec. 6, we have proved in Nuprl (1) a fully unsquashed version of UCP using Escardó and Xu's method [45]; (2) that all real functions defined on the unit interval are uniformly continuous [40, pp.87]; and (3) that bar induction on monotone bars follows from bar induction on decidable bars following Kleene's proof [58, pp.69–73].

The results presented in this paper have either been formalized in Coq and are available both at https://github.com/vrahli/NuprlInCoq and http://www.nuprl.org/html/Nuprl2Coq/; or they have been formalized in Nuprl and are available at http://www.nuprl.org/LibrarySnapshots/Published/Version1/Standard/continuity/index.html for results related to continuity, at http://www.nuprl.org/LibrarySnapshots/Published/Version1/Standard/int_2/index.html for results related to the fan theorem, and at http://www.nuprl.org/LibrarySnapshots/Published/Version1/Standard2/reals/index.html for results related to real analysis.

2. Nuprl

Nuprl is an interactive theorem prover that implements a type theory called Constructive Type Theory (CTT) [7, 28]. Nuprl's CTT "mostly" differs from other similar constructive type theories such as the ones implemented by Agda [3, 19], Coq [15, 36], or Idris [20, 56], in the sense that CTT is an *extensional* type theory (i.e., propositional and definitional equality are identified [53]) with types of partial functions [32, 37, 90]. This section presents some key aspects of Nuprl that will be used in the rest of this paper.

2.1 Nuprl's Computation System

Fig. 1 presents a subset of Nuprl's syntax and small-step operational semantics [7, 10]. Nuprl's programming language is an untyped (à la Curry), lazy and applied (with pairs, injections, a fixpoint operator,...) λ-calculus. For efficiency, integers are primitive and Nuprl provides operations on integers such as addition, subtraction,..., a test for equality and a "less than" operator. Nuprl also has what we call *canonical form tests* [83] such as `ifint`, which are used to distinguish between our different kinds of values. These canonical form tests are especially useful when working with (non-disjoint) union types, which are sometimes easier to work with than disjoint unions because one does not need injections.

A term is either a variable, a value (or canonical term), or a non-canonical term. Non-canonical terms have one or two *principal arguments* (marked using boxes in Fig. 1). A principal argument of a term t is a term that has to be evaluated to a canonical form before checking whether t can be reduced further. For example the application $f(a)$ diverges if f diverges, and the canonical form test $\texttt{ifaxiom}(t, a, b)$ diverges if t diverges.

Nuprl uses a uniform syntax for terms [9, 10], and the terms in Fig. 1 are "display forms" for some specific Nuprl terms. An advantage of having a uniform syntax is that operations that work uniformly on terms are easier to define—they do not have repetitive cases as when using one constructor per operator. In Nuprl a term is of the form $\theta(\overline{b})$, where θ is its operator, and $\overline{b}$ is a list of *bound terms*. A bound term b is of the form $\overline{l}.t$, where $\overline{l}$ is a variable list. For example, the underlying representation of a λ-abstraction is $\{\text{lambda}\}(x.t)$. For convenience, we use the uniform syntax to, e.g., define Howe's computational equivalence relation below.

Fig. 1 also shows part of Nuprl's small-step operational semantics. We omit the rules that reduce principal arguments such as: if $t_1 \mapsto t_2$ then $t_1\ u \mapsto t_2\ u$. As usual, $\mapsto^*$ is the reflexive and transitive closure of $\mapsto$, and $t_1 \mapsto^k t_2$ is defined inductively on k: $t \mapsto^0 t$ and $t_1 \mapsto^{k+1} t_2$ if there exists a t such that $t_1 \mapsto t$ and $t \mapsto^k t_2$.

We now define a few useful abstractions:

$$\begin{array}{lll} \bot = \texttt{fix}(\lambda x.x) & \mathbb{N}_? & = \mathbb{N} \cup \texttt{Unit} \\ \texttt{tt} = \texttt{inl}(\star) & \texttt{isint}(t) & = \texttt{ifint}(t, \texttt{tt}, \texttt{ff}) \\ \texttt{ff} = \texttt{inr}(\star) & \texttt{isl}(t) & = \texttt{if}\ t\ \texttt{then tt else ff} \end{array}$$

$$\texttt{if}\ t_1\ \texttt{then}\ t_2\ \texttt{else}\ t_3 = \texttt{case}\ t_1\ \texttt{of inl}(x) \Rightarrow t_1 \mid \texttt{inr}(x) \Rightarrow t_2$$

We sometimes write $a =_T b$ for the type $a = b \in T$. Also, we sometimes write b for $(\texttt{if}\ b\ \texttt{then Unit else Void})$, where `Unit` and `Void` can, e.g., be defined as $0 =_{\mathbb{Z}} 0$ and $0 =_{\mathbb{Z}} 1$ respectively. We define `True` as `Unit` and `False` as `Void`.

2.2 Howe's Computational Equivalence

It turns out that Nuprl's type system is not only closed under computation but more generally under Howe's computational equivalence $\sim$, which he proved to be a congruence [54]. In Nuprl, in any context C, when $t \sim t'$ we can rewrite t into t' without having to prove anything about types. We rely on this relation to prove equalities between programs (bisimulations) without concern for typing [83]. Howe's computational equivalence is defined on closed terms as follows: $t \sim u$ if $t \preccurlyeq u \ \wedge\ u \preccurlyeq t$. Howe coinductively defines the approximation (or simulation) relation $\preccurlyeq$ as the largest relation R on closed terms such that $R \subset [R]$, where $[\cdot]$ is the following closure operator (also defined on closed terms): $t\ [R]\ u$ if whenever t computes to a value $\theta(\overline{b})$, then u also computes to a value $\theta(\overline{b'})$ such that $\overline{b}\ R\ \overline{b'}$. To make that precise we have to extend R to open and bound terms: see [9, 10, 54] for details. By definition, one can derive, e.g., that $\bot \preccurlyeq t$ for all closed term t.

2.3 Nuprl's Type System

Following Allen's PER semantics, Nuprl's types are defined as partial equivalence relations (PERs) on closed terms [5, 6]. Allen's PER semantics can be seen as an inductive-recursive definition of: (1) an inductive relation $T_1 \equiv T_2$ that expresses type equality; and (2) a recursive function $a \equiv b \in T$ that expresses equality in a type. We write $\texttt{type}(T)$ for $T \equiv T$, and $t \in T$ for $t \equiv t \in T$. Among other things, it follows that the (theoretical) proposition $a = b \in T$ is true (inhabited by $\star$) iff $a \equiv b \in T$ holds in the meta-theory. See [9, 10] for more details.

Nuprl's type system includes Martin-Löf dependent types, identity (or equality) types, a hierarchy of universes, W types, union and intersection types, quotient types [30], set types, and partial types [37]. The top part of Fig. 1 lists some of Nuprl's types. Among these, `Base` is the type of all closed terms of the computation system with $\sim$ as its equality. The type $t_1 \preceq t_2$ is true if the meta-theoretical statement $t_1 \preccurlyeq t_2$ is true, and $t_1 \preceq t_2$ and $t_3 \preceq t_4$ are equal types if $(t_1 \preccurlyeq t_2 \iff t_3 \preccurlyeq t_4)$. Similarly the type $t_1 \simeq t_2$ is true if $t_1 \sim t_2$ is true, and $t_1 \simeq t_2$ and $t_3 \simeq t_4$ are equal types if $(t_1 \sim t_2 \iff t_3 \sim t_4)$ (see [83] as well as Appendices A and B for more details). For example, it is enough to prove that t_1 and t_2 are members of `Base` to prove that $t_1 \simeq t_2$ is a type. Also, it turns out that $t \simeq t$ is a true type in any context. These types allow us, to some extent, to reason about Nuprl's computation system directly in the theory. Nuprl has a rich type theory that makes type checking undecidable. In practice this is mitigated by type inference and type checking heuristics implemented as tactics.

We have implemented Nuprl's term language, its computation system, Howe's $\sim$ relation, and Allen's PER semantics in Coq [9, 10]. We have also showed that Nuprl is consistent by (1) proving that Nuprl's inference rules are valid w.r.t. Allen's PER semantics, and (2) proving that `False` is not inhabited. Using these two facts, we derive that there cannot be a proof derivation of `False`, i.e., Nuprl is consistent. (In addition to [9, 10], see also Appendix A for more details regarding Nuprl's consistency.)

We are using our Coq formalization to prove all the inference rules of Nuprl, and have already verified a large number of them. This paper presents extensions we made to Nuprl in order to prove $\texttt{SCP}_{\downarrow}$. It includes adding some *nominal features* such as a *fresh* operator, *named exceptions*, and *exception handlers*. Using our Coq formalization, we provide in Sec. 3 a simple proof that $\texttt{WCP}_{\downarrow}$ is true w.r.t. Nuprl's PER semantics using the fact that $\bot$ diverges, and in Sec. 4 we prove $\texttt{SCP}_{\downarrow}$ using the nominal features mentioned above.

3. Weak Continuity Principle

Our proof of $\texttt{WCP}_{\downarrow}$ uses $\bot$ and the fact that it diverges. For further details regarding this proof conducted in our implementation of

$v \in \texttt{Value} ::= vt$ (type) $\mid i$ (integer) $\mid \texttt{inl}(t)$ (left injection) $\mid \texttt{inr}(t)$ (right injection) $\mid \star$ (axiom) $\mid \langle t_1, t_2\rangle$ (pair) $\mid \lambda x.t$ (lambda)

$vt \in \texttt{Type} ::= \mathbb{Z}$ (integer) $\mid t_1 = t_2 \in t$ (equality) $\mid t_1//t_2$ (quotient) $\mid \mathbb{U}_i$ (universe) $\mid \mathbf{\Pi} x{:}t_1.t_2$ (product) $\mid \cup x{:}t_1.t_2$ (union) $\mid t_1{+}t_2$ (disjoint union) $\mid \bar{t}$ (partial) $\mid \mathbf{\Sigma} x{:}t_1.t_2$ (sum) $\mid \cap x{:}t_1.t_2$ (intersection) $\mid \{x : t_1 \mid t_2\}$ (set) $\mid \texttt{W}(x{:}t_1.t_2)$ (W) $\mid \texttt{Base}$ (base) $\mid t_1 \preceq t_2$ (simulation) $\mid t_1 \simeq t_2$ (bisimulation)

$t \in \texttt{Term} ::= x$ (variable) $\mid v$ (value) $\mid \boxed{t_1}\ t_2$ (application) $\mid \texttt{fix}(\boxed{t})$ (fixpoint) $\mid \texttt{let}\ x := \boxed{t_1}\ \texttt{in}\ t_2$ (call-by-value) $\mid \texttt{let}\ x, y = \boxed{t_1}\ \texttt{in}\ t_2$ (spread) $\mid \texttt{if}\ \boxed{t_1}{=_\mathbb{Z}}\boxed{t_2}\ \texttt{then}\ t_3\ \texttt{else}\ t_4$ (integer equality) $\mid \texttt{case}\ \boxed{t_1}\ \texttt{of}\ \texttt{inl}(x) \Rightarrow t_2 \mid \texttt{inr}(y) \Rightarrow t_3$ (decide) $\mid \texttt{if}\ \boxed{t_1}{<}\boxed{t_2}\ \texttt{then}\ t_3\ \texttt{else}\ t_4$ (less than) $\mid \texttt{ifint}(\boxed{t_1}, t_2, t_3)$ (integer test) $\mid \texttt{ifaxiom}(\boxed{t_1}, t_2, t_3)$ (axiom test)

$(\lambda x.F)\ a \mapsto F[x\backslash a]$
$\texttt{let}\ x, y = \langle t_1, t_2\rangle\ \texttt{in}\ F \mapsto F[x\backslash t_1; y\backslash t_2]$
$\texttt{if}\ i_1{=_\mathbb{Z}}i_2\ \texttt{then}\ t_1\ \texttt{else}\ t_2 \mapsto t_1$, if $i_1 = i_2$
$\texttt{if}\ i_1{=_\mathbb{Z}}i_2\ \texttt{then}\ t_1\ \texttt{else}\ t_2 \mapsto t_2$, if $i_1 \neq i_2$
$\texttt{if}\ i_1{<}i_2\ \texttt{then}\ t_1\ \texttt{else}\ t_2 \mapsto t_1$, if $i_1 < i_2$
$\texttt{if}\ i_1{<}i_2\ \texttt{then}\ t_1\ \texttt{else}\ t_2 \mapsto t_2$, if $i_1 \not< i_2$
$\texttt{case}\ \texttt{inl}(t)\ \texttt{of}\ \texttt{inl}(x) \Rightarrow F \mid \texttt{inr}(y) \Rightarrow G \mapsto F[x\backslash t]$

$\texttt{fix}(v) \mapsto v\ \texttt{fix}(v)$
$\texttt{let}\ x := v\ \texttt{in}\ t \mapsto t[x\backslash v]$
$\texttt{ifint}(i, t_1, t_2) \mapsto t_1$
$\texttt{ifint}(v, t_1, t_2) \mapsto t_2$, if v is not an integer
$\texttt{ifaxiom}(\star, t_1, t_2) \mapsto t_1$
$\texttt{ifaxiom}(v, t_1, t_2) \mapsto t_2$, if v is not $\star$
$\texttt{case}\ \texttt{inr}(t)\ \texttt{of}\ \texttt{inl}(x) \Rightarrow F \mid \texttt{inr}(y) \Rightarrow G \mapsto G[y\backslash t]$

Figure 1 Syntax (top) and operational semantics (bottom) of a subset of Nuprl

Nuprl in Coq, the interested reader is invited to look at https://github.com/vrahli/NuprlInCoq/blob/master/continuity/continuity_roadmap.v. The same proof would not work for $\downarrow$, because using $\downarrow$ we can compute the modulus of continuity of a function in the meta-theory (this computation does not have to be expressible in the theory because only $\star$ inhabits $\downarrow$-squashed types), while using $\mid$ we would have to come up with a Nuprl term t that does the computation (Sec. 4 shows how to do that), i.e., such that $t{\in}\texttt{WCP}_\mid$.

Let $F \in \mathbb{Z}^\mathbb{Z} \to \mathbb{Z}$ and $f \in \mathbb{Z}^\mathbb{Z}$ (we use $\mathbb{Z}$ here instead of $\mathbb{N}$, but we proved a slightly more general result for functions of type $T^\mathbb{Z} \to \mathbb{Z}$ where T is a non-empty subtype of $\mathbb{Z}$, such as $\mathbb{N}$ or $\mathbb{N}_2$).

Step 1. By typing, this means that $F(f) \in \mathbb{Z}$, i.e., $F(f)$ computes to an integer i.

Step 2. It might seem that in that computation f only gets applied to integers, however, this is not necessarily true in an untyped language such as Nuprl. To remedy this issue, let $\texttt{force}(f) = \lambda x.\texttt{let}\ x := x + 0\ \texttt{in}\ f\ x$. Because $f = \texttt{force}(f) \in \mathbb{Z}^\mathbb{Z}$, by typing again we get $F(\texttt{force}(f)) \mapsto^* i$. Let us call that computation C_1. We use `force` to ensure that f's arguments are integers. If $\texttt{force}(f)$ was to be applied to a term that is not an integer then the computation would either get stuck or diverge. We know that this cannot happen because $F(\texttt{force}(f)) \mapsto^* i$.

Step 3. Let $\texttt{bound}(t, b) = \texttt{let}\ x := t\ \texttt{in}\ \texttt{if}\ |x|{<}b\ \texttt{then}\ x\ \texttt{else}\ \bot$. By computation we prove that there exists a number b such that $F(\lambda x.\texttt{let}\ x := \texttt{bound}(x, b)\ \texttt{in}\ f\ x) \mapsto^* i$. We can get such a b in the meta-theory by computing the largest number occurring in the computation C_1, i.e., if $t_1 = F(\texttt{force}(f)) \mapsto t_2 \mapsto \cdots \mapsto i = t_n$, then let b be the largest number occurring in one of the t_i. We have to squash `WCP`'s existential quantifier using $\downarrow$ because this meta-theoretical computation of b is not a Nuprl term. We prove this step using a *simulation* technique that we will reuse over and over again in this paper. We prove that given a context G, if $G[x{+}0]$ computes to a value v then $G[\texttt{bound}(x, b)]$ also computes to v, assuming that b is greater that any number occurring in the computation $G[x + 0] \mapsto^* v$. Note that we have not yet used the fact that $\bot$ diverges. This will be used in step 5. Let us call C_2 the computation $F(\lambda x.\texttt{let}\ x := \texttt{bound}(x, b)\ \texttt{in}\ f\ x) \mapsto^* i$.

Step 4. We can now instantiate our conclusion using b. It remains to prove that $\mathbf{\Pi} g{:}\mathbb{Z}^\mathbb{Z}.f =_{\mathbb{Z}^\mathbb{Z}_b} g \to F(f) =_\mathbb{Z} F(g)$. Because f and g agree up to b, and because the computation C_2 converges, by computation we know that $F(\lambda x.\texttt{let}\ x := \texttt{bound}(x, b)\ \texttt{in}\ g\ x) \mapsto^* i$. We prove this by showing that given a context G, if $G[\texttt{let}\ x := \texttt{bound}(x, b)\ \texttt{in}\ f\ x]$ computes to a value, then $G[\texttt{let}\ x := \texttt{bound}(x, b)\ \texttt{in}\ g\ x]$ computes to the same value. We still have not used the fact that $\bot$ diverges, because we could use any number in `bound`'s definition instead of $\bot$, such as 0, and make sure that $0 < b$.

Step 5. Again by computation: $F(\texttt{force}(g)) \mapsto^* i$. We prove this by showing that given a context G, if $G[\texttt{bound}(x, b)]$ computes to a value then $G[x + 0]$ computes to the same value because the "less than" operator in `bound`'s definition ensures that x is an integer, and because we know that $G[\texttt{bound}(x, b)]$ *does not diverge*.

Step 6. Finally, by typing, $F(g) \mapsto^* i$, i.e., $F(f) =_\mathbb{Z} F(g)$.

4. Strong Continuity Principle

We now prove $\texttt{SCP}_\mid$ [58, pp.69–73] (Sec. 5 shows that $\texttt{SCP}_\mid$ and $\texttt{WCP}_\mid$ are equivalent). We need to come up with a Nuprl term of type $\mathbf{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}{+}\texttt{Unit}$ that checks whether we have reached the modulus of continuity of a function. For that, we now use exceptions as a probing mechanism to compute the modulus of continuity of a function. Instead of $\texttt{SCP}_\mid$, we prove the following equivalent but slightly simpler statement [58, pp.71-72] (where the `T` in `SCPT` is for Test—see below):

$$\begin{aligned}\texttt{SCPF}(F) = \mid \mathbf{\Sigma} M{:}(\mathbf{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_?).\\ \mathbf{\Pi} f{:}\mathcal{B}.\\ \downarrow\mathbf{\Sigma} n{:}\mathbb{N}.M\ n\ f =_\mathbb{N} F(f)\\ \wedge\ \mathbf{\Pi} n{:}\mathbb{N}.\\ \texttt{isint}(M\ n\ f) \to M\ n\ f =_\mathbb{N} F(f)\\ \texttt{SCPT} = \mathbf{\Pi} F{:}\mathcal{B} \to \mathbb{N}.\ \texttt{SCPF}(F)\end{aligned}$$

Using our Coq formalization and making use of computations on terms that are only possible in the meta-theory, we proved that `SCPT` is true w.r.t. the PER semantics of Nuprl extended with the nominal features mentioned above. We then proved directly in Nuprl that `SCPT` and $\texttt{SCP}_\mid$ are equivalent. We prove `SCPT` rather than $\texttt{SCP}_\mid$ mainly because its realizer is simpler. Intuitively, the M part of `SCPT`'s realizer is a simple test function (top), while the one for $\texttt{SCP}_\mid$ is a recursive search function of the form (bottom):[5]

```
fun test n f =
  let exception e in
  (let v = F (fun x => if x < n then f x
                       else raise e)
   in Some v) handle e => None
```

[5] In both functions, None means that n is less than the modulus of continuity of F at f. In the test function, Some v means that v is F(f) and n is greater than or equal to the modulus of continuity of F at f, while the search function returns F(f) only when n is the modulus of continuity of F at f (and not when n is past the modulus as in the test function).

```
let fun search n m f =
      if m <= 0 then test n f
      else case test m f of
           | Some k => None
           | None => search n (m - 1) f
           end
in search n (n - 1) f
```

4.1 Extension of Nuprl's Computation System

4.1.1 Syntax

We extend Nuprl with *names* (or unguessable atoms [16]), *named exceptions*, *exception handlers*, and a *fresh* operator as follows:

v	$::= \cdots \mid \boldsymbol{a}$	(name value)
vt	$::= \ldots$	
	$\mid \texttt{Name}$	(name type)
	$\mid \texttt{Exc}(t_1, t_2)$	(exception type)
e	$::= \texttt{exc}(t_1, t_2)$	(exception)
t	$::= \ldots$	
	$\mid e$	(exception)
	$\mid \texttt{if } \boxed{t_1} = \boxed{t_2} \texttt{ then } t_3 \texttt{ else } t_4$	(name equaliy)
	$\mid \boldsymbol{\nu} x.\boxed{t}$	(fresh)
	$\mid \texttt{try}_n \boxed{t} \texttt{ with } x.c$	(try/catch)

`Name` is a type of names (constants) and $\boldsymbol{a}$ stands for a name. Names were introduced in Nuprl to reason about logical foundations for security [16]. To account for names, Allen generalized his PER semantics [6] to a so-called *supervaluation* semantics that quantifies over all possible implementations of the `Name` type [4]. Names come with two meta-theoretical operations: a fresh operator to generate a fresh name w.r.t. a list of names, and a test for equality. As in Pitts and Stark's ν-calculus [79] or Odersky's $\lambda\nu$-calculus [74], we add two corresponding operators to Nuprl.

Our exceptions and handlers are similar to Lebresne's [64]. In Nuprl, an exception e has two subterms: the first one is e's name and the second one is some piece of data that can be used if e is caught. The type $\texttt{Exc}(t_1, t_2)$ is the type of exceptions with names of type t_1 and data of type t_2. In general exceptions can be named with terms other than names. For example, if $\boldsymbol{a}$ and $\boldsymbol{b}$ are names, both $\texttt{exc}(\boldsymbol{a}, 0)$ and $\texttt{exc}(\boldsymbol{b}, 0)$ have type $\texttt{Exc}(\texttt{Name}, \mathbb{Z})$ (among others); and $\texttt{exc}(1, 0)$ has type $\texttt{Exc}(\mathbb{Z}, \mathbb{Z})$. We also add exception handlers of the form $\texttt{try}_n\ t \texttt{ with } x.c$, where t is the term we try to evaluate, and $c[x\backslash d]$ is the code we run if we catch an exception with name n and data d. Therefore, a handler cannot catch all exceptions. A canonical operator is now either a value or an exception.

Let us define a few useful abstractions/abbreviations:

$$\begin{array}{ll} \texttt{Name}_n & = \{x : \texttt{Name} \mid x \simeq n\} \\ \texttt{Exc}_n(T) & = \texttt{Exc}(\texttt{Name}_n, T) \\ \texttt{Exc}_n & = \texttt{Exc}_n(\texttt{Unit}) \\ T?_n & = T \cup \texttt{Exc}_n \\ \texttt{exc}_n & = \texttt{exc}(n, \star) \\ \texttt{try}_n\ t & = \texttt{try}_n\ t \texttt{ with } x.\star \end{array}$$

If T is not an exception type, $T?_n$ is the type of terms that either compute to elements of type T or that compute to exceptions with name n and data $\star$.

The type $T?_n$ is similar to Lebresne's type $A \uplus \{\epsilon\}$, where A is a type and ϵ is an exception [63, 64]. In addition Lebresne also introduces *corruption* types of the form $A^{\{\epsilon\}}$. A term in $A^{\{\epsilon\}}$ is a term in A where some part has been replaced by the exception ϵ. As he mentions, an expression of that type does not necessarily evaluates to an exception. For example, if Nuprl had such a type, $\texttt{inl}(\texttt{exc}_{\boldsymbol{a}})$ could be of type $(\mathbb{N}+\texttt{Unit})^{\{\boldsymbol{a}\}}$. We leave adding corruption types to Nuprl for future work (Sacchini [85] shows that corruption in the presence of dependent types has interesting consequences).

Exceptions are a standard programming language feature. In the interactive theorem proving realm they are "well-adapted to programming strategies which may be (in fact usually are) inapplicable to certain goals" [51, pp.11]. However, exceptions are often not accounted for in types. As mentioned above, Lebresne's Fx system [64] provides type constructors to express two different levels of *corruption*. Lebresne [64] mentions that to get exceptions one could either directly encode them in the language (e.g., using monads) or add them as primitive. We decided to add them as primitives for the same reasons (e.g., compositionality) stated in his paper. David and Mounier [39] introduced EX_2 as an extension of Krivine's FA_2 system [62] with exceptions. As in Nuprl, both Fx and in EX_2 implement call-by-name exceptions. Also, in all three systems exceptions and handlers are named, and handlers can only catch exceptions with the correct name.

4.1.2 Operational Semantics of $\boldsymbol{\nu}$

Let us now precisely define how fresh and handlers compute. A fresh expression of the form $\boldsymbol{\nu} x.t$ computes differently depending on whether t is a variable, a canonical term, or a non-canonical term. Let us consider each of these cases.

Variable. If t is the variable x then $\boldsymbol{\nu} x.t$ reduces to itself and therefore diverges. Therefore, one can prove that $\boldsymbol{\nu} x.x \sim \bot$. This differs both from Odersky's [74] approach where $\boldsymbol{\nu} x.x$ is stuck and from Pitts' approach [77] where $\boldsymbol{\nu} x.x$ is a normal form. If t reduces to another variable than x then the computation gets stuck because the term is open.

Non-canonical. If t is non-canonical then

$$\boldsymbol{\nu} x.t \mapsto \boldsymbol{\nu} x.u[\boldsymbol{a}\backslash x] \qquad \text{if} \qquad t[x\backslash \boldsymbol{a}] \mapsto u$$

where $\boldsymbol{a}$ is a fresh name w.r.t. t (written $\boldsymbol{a}\#t$), and $t[\boldsymbol{a}\backslash u]$ is a capture avoiding substitution function on names (similar to the usual substitution operation on variables). This ensures that fresh names do not escape the scope of $\boldsymbol{\nu}$ expressions. As expected (if $x \neq y$):

$$\boldsymbol{\nu} x.\boldsymbol{\nu} y.\texttt{if } x{=}y \texttt{ then tt else ff} \mapsto^* \texttt{ff}$$

We cannot simply reduce $\boldsymbol{\nu}$ as follows: $\boldsymbol{\nu} x.t \mapsto t[x\backslash \boldsymbol{a}]$, because Howe's computational equivalence would not be a congruence. For example, $\boldsymbol{\nu} x.\texttt{inl}(x) \mapsto \texttt{inl}(\boldsymbol{a})$ and $(\texttt{let } y := \boldsymbol{a} \texttt{ in } x) \sim x$ but $\boldsymbol{\nu} x.\texttt{inl}(\texttt{let } y := \boldsymbol{a} \texttt{ in } x) \not\mapsto^* \texttt{inl}(\boldsymbol{a})$.

Canonical. If t is a canonical form (a value or an exception), then we "push" $\boldsymbol{\nu}$ "down" the expression as in Odersky's $\lambda\nu$-calculus [67, 74] (as opposed to using, e.g., stateful dynamic allocation [67] or the notion of *prevalues* [57], which are values prefixed with a list of "fresh name" binders):

$$\boldsymbol{\nu} x.t \ \mapsto \ \Downarrow_x t$$

where $\Downarrow$ computes as follows on terms:

$$\Downarrow_x \theta(b_1; \cdots; b_n) = \theta(\Downarrow_x b_1; \cdots; \Downarrow_x b_1)$$

and as follows on bound terms:

$$\Downarrow_x (\bar{l}.t) = \bar{l}.\boldsymbol{\nu} x'.t$$

where, in order to avoid variable capture, x' is x if $x \notin \bar{l}$, and a fresh variable w.r.t. t otherwise. For example $\boldsymbol{\nu} x.\langle 1, x\rangle \mapsto \langle \boldsymbol{\nu} x.1, \boldsymbol{\nu} x.x\rangle$ and $\boldsymbol{\nu} x.\lambda y.t \ \mapsto \ \lambda y.\boldsymbol{\nu} x.t$ if $x \neq y$. Note that when $x \in \bar{l}$, we could have defined $\Downarrow_x (\bar{l}.t)$ to be $\bar{l}.t$. However, this would make the definition less uniform and therefore harder to reason about. To this effect, we proved $\boldsymbol{\nu} x.t \sim t$ if t is closed.

4.1.3 Operational Semantics of `try`

Handlers of the form $\texttt{try}_n\ e \texttt{ with } x.c$ catch exceptions of the form $\texttt{exc}(n, d)$. For example,

$$\texttt{try}_{\boldsymbol{a}}\ (1 + \texttt{exc}(\boldsymbol{a}, \lambda x.x + 1)) \texttt{ with } f.f(2) \mapsto^* 3$$

When its principal argument is non-canonical or a variable, a handler computes exactly like the other non-canonical operators (except $\boldsymbol{\nu}$). Let us consider the exception and value cases.

Exception. If t is an exception of the form $\texttt{exc}(n, d)$ then we have to check whether the handler has the right name as follows:

$$\begin{array}{l}\texttt{try}_m\ \texttt{exc}(n, d)\ \texttt{with}\ x.c\\ \mapsto \texttt{if}\ m{=}n\ \texttt{then}\ c[x\backslash d]\ \texttt{else}\ \texttt{exc}(n, d)\end{array}$$

This computational rule also has the following effect that if m computes to an exception e, then $\texttt{try}_m\ \texttt{exc}(n, d)\ \texttt{with}\ x.c \mapsto^* e$. Also, if m is a name and n computes to an exception e then $\texttt{try}_m\ \texttt{exc}(n, d)\ \texttt{with}\ x.c \mapsto^* e$.

Value. A naive way or reducing a handler when its principal argument is a value would be to simply return the value as follows:

$$\texttt{try}_n\ v\ \texttt{with}\ x.c \mapsto v$$

However, note that in the case where the principal argument of a handler is an exception, we have to evaluate the "name" part of the handler to check whether the exception has the correct name. This means that if we were to simply return the value here and if the "name" part was $\bot$ for example, raising an exception in an expression that is "well-behaved" could cause the expression to diverge. For example, using the above rule: $\texttt{try}_\bot\ 1 \mapsto 1$, and if we replace 1 by $\texttt{exc}_{\boldsymbol{a}}$, then $\texttt{try}_\bot\ \texttt{exc}_{\boldsymbol{a}}$ diverges. This is undesirable, especially in the context of using exceptions to probe a function, e.g., to compute its modulus of continuity. Therefore, instead of simply returning the value, we first check that n is something that we can compare:

$$\texttt{try}_n\ v\ \texttt{with}\ x.c \mapsto \texttt{if}\ n{=}n\ \texttt{then}\ v\ \texttt{else}\ \bot$$

4.2 Howe's Computational Equivalence in the Presence of $\boldsymbol{\nu}$

To prove that $\sim$ is a congruence, Howe first proves that $\preccurlyeq$ is a congruence [54]. Unfortunately, this is not easy to prove directly. Howe's "trick" was to define another relation $\preccurlyeq^*$, which is a congruence and contains $\preccurlyeq$ by definition.

Howe's definition of $\preccurlyeq^*$ does not use types, but to account for the fact that the binders of $\boldsymbol{\nu}$ expressions are only meant to be names (as opposed to the binders of, e.g., λ-abstractions, which can be substituted by any term when applied), rather than turn Nuprl into a typed language, we added "simple" type information to the definition of $\preccurlyeq^*$. We define a function BT that, for a given operator, returns the types of the binders of its bound terms. The type of a binder can either be NAME or ANY. $\texttt{BT}(\boldsymbol{\nu}) = [[\texttt{NAME}]]$ because $\boldsymbol{\nu}$ has one subterm (the outer brackets) that has one binder (the inner brackets). The type of all the other binders is ANY. For example, $\texttt{BT}(\lambda) = [[\texttt{ANY}]]$ because a λ-abstraction has one subterm which has one binder. When extending the definition of $\preccurlyeq^*$ from terms to bound terms, BT is used to restrict what terms can be substituted for free variables. This modification of $\preccurlyeq^*$'s definition was inspired by Gordon's [50] and Jeffrey and Rathke's [57] adaptations of Howe's method to typed λ-calculi. It is interesting to note that until we added the $\boldsymbol{\nu}$ operator to Nuprl, there was no need to use type information in the proof that $\sim$ is a congruence.

Howe defines $t \preccurlyeq^* u$ by induction on t: if t is a variable then $t \preccurlyeq^* u$ if $t \preccurlyeq u$; and if t is of the form $\tau(\overline{b})$ then $t \preccurlyeq^* u$ if there exists $\overline{b'}$ such that $\overline{b} \preccurlyeq^* \overline{b'}$ and $\tau(\overline{b'}) \preccurlyeq u$. To prove that $\preccurlyeq^*$ and $\preccurlyeq$ are equivalent and therefore that $\preccurlyeq$ and $\sim$ are congruences, it suffices to prove that $\preccurlyeq^*$ respects computation, i.e., given that $t \preccurlyeq^* u$, if t computes to a value of the form $\theta(\overline{b})$ then u also computes to a value $\theta(\overline{b'})$ such that $\overline{b} \preccurlyeq^* \overline{b'}$. Howe's Lemma 2 in [54] shows that this is true when t is a value.

Howe then defines a condition called *extensionality* that non-canonical operators of lazy computation systems have to satisfy for $\preccurlyeq^*$ to imply $\preccurlyeq$, and therefore for $\preccurlyeq$ and $\sim$ to be congruences. First, we extended all these definitions to deal with the fact that canonical forms can either be values or exceptions. Then, using our new definition of $\preccurlyeq^*$ we were able to prove that $\boldsymbol{\nu}$ is extensional (see Appendix D for more details).

4.3 Consistency

As mentioned above, Nuprl's consistency follows from the fact that all its inference rules are valid w.r.t. Allen's PER semantics and from the fact that False is not inhabited. In addition to extending Nuprl's computation system, and fixing its properties including Howe's computational equivalence relation, we had to re-run all the proofs that Nuprl's inference rules are valid. Most of these rules and proofs did not have to change. The only one that had to change is discussed in details in Appendix C (see Appendices A and B for details regarding the validity of rules). Let us summarize this discussion here.

First, note that because exceptions are canonical forms as mentioned in Sec. 4.1.1 above, if $a \mapsto^* \texttt{exc}(t_1, t_2)$ then $a \preccurlyeq b$ if there exists u_1 and u_2 such that $b \mapsto^* \texttt{exc}(u_1, u_2)$, $t_1 \preccurlyeq u_1$, and $t_2 \preccurlyeq u_2$. Therefore, even though we cannot have a canonical form test (such as ifint or ifaxiom) for exceptions that would check whether a term computes to an exception because we cannot catch an exception without having its name (i.e., we have no way of catching all exceptions), we can define a proposition $\texttt{isexc}(t)$ that asserts that a term t computes to an exception as follows: $\texttt{isexc}(t) = \texttt{exc}_\bot \preceq t$, where $\texttt{exc}_\bot = \texttt{exc}(\bot, \bot)$. Similarly, the following proposition $\texttt{halts}(t)$ asserts that t computes to a value: $\texttt{halts}(t) = \star \preceq (\texttt{let}\ x := t\ \texttt{in}\ \star)$. By definition of Howe's approximation relation, before adding exceptions, when proving a proposition of the form $t_1 \preceq t_2$ we could assume $\texttt{halts}(t_1)$. This was captured by our old [convergence] inference rule described in Appendix C. This is no longer true because we also have to consider the case where t_2 is an exception. To that effect our new [convergence] inference rule generates (among others) two subgoals: one that assumes $\texttt{halts}(t_1)$ and one that assumes $\texttt{isexc}(t_1)$. Alternatively, we could capture that a term t computes to either a value or an exception using the type: $\texttt{exc}_\bot \preceq (\texttt{let}\ x := t\ \texttt{in}\ \texttt{exc}_\bot)$. We have not yet investigated the usefulness of such a type.

4.4 Computing the Modulus of Continuity

We now have the tools in hand to compute the modulus of continuity of a functional using exceptions as described above:

$$\begin{array}{ll}\texttt{force}(k, t) & = \texttt{if}\ k{<}0\ \texttt{then}\ \bot\ \texttt{else}\ t\\ \texttt{bound}(n, f, e, k) & = \texttt{force}(k, \texttt{if}\ k{<}n\ \texttt{then}\ f(k)\ \texttt{else}\ \texttt{exc}_e)\\ \texttt{bound}(n, f, e) & = \lambda x.\texttt{bound}(n, f, e, x)\\ \texttt{test}(F, n, f) & = \boldsymbol{\nu} x.\texttt{try}_x\ F(\texttt{bound}(n, f, x))\\ \texttt{M}(F) & = \lambda n.\lambda f.\texttt{test}(F, n, f)\end{array}$$

i.e., unfolding the definitions, $\texttt{M}(F)$ is

$$\lambda n.\lambda f.\boldsymbol{\nu} x.\texttt{try}_x\ F\left(\lambda y.\begin{array}{l}\texttt{if}\ y{<}0\ \texttt{then}\ \bot\\ \texttt{else}\ \left(\begin{array}{l}\texttt{if}\ y{<}n\ \texttt{then}\ f(y)\\ \texttt{else}\ \texttt{exc}_x\end{array}\right)\end{array}\right)$$

Also, let $\texttt{force}(f) = \lambda x.\texttt{force}(x, f(x))$. As in our proof of $\texttt{WCP}_\downarrow$, we will partly use typing, partly use computation to prove that $\texttt{M}(F)$ is indeed our witness for SCPT. This is why bound starts off by checking whether its argument x is an integer less than 0. If a computation that uses bound converges and along the way applies f to some term k, we will be guaranteed that k is a natural number.

4.5 Well-Typedness

To prove SCPT, we first prove that $\texttt{M}(F)$ has type $\boldsymbol{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_?$. As mentioned above, this term does not respect computation, it is not functional over $F{\in}\mathcal{B} \to \mathbb{N}$. However, given a

term F, we can still prove that $\mathtt{M}(F)$ has the right type. For that, we have to prove that for all closed terms n and m such that $n{\equiv}m{\in}\mathbb{N}$, and for all closed terms f and g such that $f{\equiv}g{\in}\mathbb{N}^{\mathbb{N}_n}$, we have $\mathtt{test}(F,n,f){\equiv}\mathtt{test}(F,m,g){\in}\mathbb{N}_?$. By definition, $n{\equiv}m{\in}\mathbb{N}$ means that there exists a natural number k such that both n and m compute to k. Therefore, let us assume $f{\equiv}g{\in}\mathbb{N}^{\mathbb{N}_k}$ and let us prove $\mathtt{test}(F,k,f){\equiv}\mathtt{test}(F,k,g){\in}\mathbb{N}_?$. Unfolding `test`'s definition, we have to prove

$$\begin{array}{l}\boldsymbol{\nu}x.\mathtt{try}_x\ F(\mathtt{bound}(k,f,x))\\ {\equiv}\boldsymbol{\nu}x.\mathtt{try}_x\ F(\mathtt{bound}(k,g,x))\\ {\in}\mathbb{N}_?\end{array}$$

As we show below in Sec. 4.6, to prove that it is enough to prove

$$\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(k,f,\boldsymbol{a})){\equiv}\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(k,g,\boldsymbol{a})){\in}\mathbb{N}_?$$

where $\boldsymbol{a}$ is such that $\boldsymbol{a}\#F$, $\boldsymbol{a}\#f$, and $\boldsymbol{a}\#g$. Again, it is enough to prove

$$F(\mathtt{bound}(k,f,\boldsymbol{a})){\equiv}F(\mathtt{bound}(k,g,\boldsymbol{a})){\in}\mathbb{N}_{?\boldsymbol{a}} \tag{1}$$

By typing again, from $f{\equiv}g{\in}\mathbb{N}^{\mathbb{N}_k}$, we deduce that

$$\mathtt{bound}(k,f,\boldsymbol{a}){\equiv}\mathtt{bound}(k,g,\boldsymbol{a}){\in}(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}} \tag{2}$$

A general fact about exceptions is: if $F{\in}\mathcal{B}\to\mathbb{N}$ and $\boldsymbol{a}\#F$ then

$$\mathtt{Force}(F){\in}(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}}\to\mathbb{N}_{?\boldsymbol{a}} \tag{3}$$

where $\mathtt{Force}(F)=\lambda f.F(\mathtt{force}(f))$. Is `Force` necessary? Can't we simply prove $F{\in}(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}}\to\mathbb{N}_{?\boldsymbol{a}}$? In other words, can we find a F in $\mathcal{B}\to\mathbb{N}$, such that $\boldsymbol{a}\#F$, and an f in $(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}}$ such that $F(f)$ is not in $\mathbb{N}_{?\boldsymbol{a}}$? Yes we can: take

$$\begin{array}{l}F=\lambda f.f(f(0))\\ f=\lambda x.\mathtt{let}\ z:=(\mathtt{try}_{\boldsymbol{a}}\ x\ \mathtt{with}\ z.\bot)\ \mathtt{in}\ \mathtt{exc}_{\boldsymbol{a}}\end{array}$$

(Note that in f's definition $\bot$ could be any term not in $\mathbb{N}$.) These expressions are of the right type, but $F(f)$ computes to $f(f(0))$, which computes to $f(\mathtt{exc}_{\boldsymbol{a}})$, which computes to $\mathtt{let}\ z:=\bot\ \mathtt{in}\ \mathtt{exc}_{\boldsymbol{a}}$, which diverges and is therefore not of type $\mathbb{N}_{?\boldsymbol{a}}$. Proving 3 is the crux of proving that $\mathtt{M}(F)$ is well-typed. To prove that we use the same technique as in $\mathtt{WCP}_{\downarrow}$'s proof. Given 3, it is trivial to deduce that the equality 1 is true using equality 2.

Let us now prove 3. We have to prove that for all F in $\mathcal{B}\to\mathbb{N}$, and f and g such that $f{\equiv}g{\in}(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}}$,

$$F(\mathtt{force}(f)){\equiv}F(\mathtt{force}(g)){\in}\mathbb{N}_{?\boldsymbol{a}}$$

First, we define a function `force0` so that the function $f'=\lambda x.\mathtt{force0}(x,f)$ computes as the function $f_0=\mathtt{force}(f)$, except that on natural numbers, when f_0 returns $\mathtt{exc}_{\boldsymbol{a}}$, f' returns 0 (this 0 could be any natural number):

$$\mathtt{force0}(x,f)=\mathtt{if}\ x{<}0\ \mathtt{then}\ \bot\ \mathtt{else}\ \mathtt{try}_{\boldsymbol{a}}\ f(x)\ \mathtt{with}\ z.0$$

Let $g_0=\mathtt{force}(g)$. Note that $f_0{\equiv}g_0{\in}(\mathbb{N}_{?\boldsymbol{a}})^{\mathbb{N}}$. Because f' is in $\mathcal{B}$, we get that $F(f')$ computes to a natural number. Let us now use again the same simulation technique as before. Let us prove that in any context C with no occurrence of $\boldsymbol{a}$, if $C[f']$ computes to a natural number j, then either both $C[f_0]$ and $C[g_0]$ also compute to j or both $C[f_0]$ and $C[g_0]$ compute to $\mathtt{exc}_{\boldsymbol{a}}$. We prove that by induction on the length of the reduction $C[f']\mapsto^*j$. For that we prove that if $C[f']\mapsto u$ and u computes to a canonical expression, then there exists a context C' such that $u\mapsto^*C'[f']$ and either both $C[f_0]\mapsto^*C'[f_0]$ and $C[g_0]\mapsto^*C'[g_0]$ or both $C[f_0]\mapsto^*\mathtt{exc}_{\boldsymbol{a}}$ and $C[g_0]\mapsto^*\mathtt{exc}_{\boldsymbol{a}}$. This gives us that $F(f_0){\equiv}F(g_o){\in}\mathbb{N}_{?\boldsymbol{a}}$

4.6 Interlude: Reasoning About $\boldsymbol{\nu}$

In Sec. 4.1.2 we saw how $\boldsymbol{\nu}$ computes. We show here how to reason about $\boldsymbol{\nu}$. One can prove that $\boldsymbol{\nu}x.t_1{\equiv}\boldsymbol{\nu}x.t_2{\in}T$ by proving that $t_1[x\backslash\boldsymbol{a}]{\equiv}t_2[x\backslash\boldsymbol{a}]{\in}T$, assuming $\boldsymbol{a}\#t_1$ and $\boldsymbol{a}\#t_2$, and that T is *flat*, meaning that its inhabitants compute to terms that have no subterms and that are not names, such as integers or $\star$. This follows from the way $\boldsymbol{\nu}$ computes. If $t[x\backslash\boldsymbol{a}]\mapsto^*u$ such that $\boldsymbol{a}\#t$ then $\boldsymbol{\nu}v.t\mapsto^*\boldsymbol{\nu}x.u[\boldsymbol{a}\backslash x]$. In the integer case, if $t_1[x\backslash\boldsymbol{a}]\mapsto^*i$ then $\boldsymbol{\nu}x.t_1\mapsto^*\boldsymbol{\nu}x.i$ and $\boldsymbol{\nu}x.i\mapsto i$. We get that $\boldsymbol{\nu}x.t_1\sim t_1[x\backslash\boldsymbol{a}]$. Because the union of flat types is flat, $\mathbb{N}_?$ is flat.

We can prove similar rules for the other types. For example, one can prove that $\boldsymbol{\nu}x.f_1{\equiv}\boldsymbol{\nu}x.f_2{\in}\boldsymbol{\Pi}a{:}A.B$ by proving that $\boldsymbol{\Pi}a{:}A.B$ is a type, and that for all a_1 and a_2 such that $a_1{\equiv}a_2{\in}A$, $\boldsymbol{\nu}x.f_1(a_1){\equiv}\boldsymbol{\nu}x.f_2(a_2){\in}B[a\backslash a_1]$ (see lemma `fresh_in_function` in https://github.com/vrahli/NuprlInCoq/blob/master/continuity/stronger_continuity_props1.v).

4.7 1st Condition

The first property we prove about the function `M` defined above in Sec. 4.4 is that for all f in $\mathcal{B}$, $\downarrow\boldsymbol{\Sigma}n{:}\mathbb{N}.\mathtt{M}(F)\ n\ f=_{\mathbb{N}}F(f)$. This condition says that for all f there exists a n such that `M` only requires an "initial sequence" of length n of f to compute the same result as $F(f)$. This n is therefore at least the modulus of continuity of F at f.

As before, by typing we get that $F(f){\equiv}F(\mathtt{force}(f)){\in}\mathbb{N}$. Hence, there exists a natural number k such that $F(\mathtt{force}(f))\mapsto^*k$. As in the proof of $\mathtt{WCP}_{\downarrow}$, we first compute the maximum of all the numbers occurring in that computation, and we instantiate our conclusion with b a number which is strictly greater than this maximum. We now have to prove: $\mathtt{M}(F)\ b\ f=_{\mathbb{N}}F(f)$, or equivalently $\mathtt{test}(F,b,f)=_{\mathbb{N}}F(\mathtt{force}(f))$. Unfolding `test`'s definition, we have to prove:

$$\boldsymbol{\nu}x.\mathtt{try}_x\ F(\mathtt{bound}(b,f,x)){\equiv}F(\mathtt{force}(f)){\in}\mathbb{N}$$

As in Sec. 4.5, because we're trying to prove that this $\boldsymbol{\nu}$ is in $\mathbb{N}$ and because $\mathbb{N}$ is flat, it is enough to prove for some name $\boldsymbol{a}$ such that $\boldsymbol{a}\#F$ and $\boldsymbol{a}\#f$:

$$\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(b,f,\boldsymbol{a})){\equiv}F(\mathtt{force}(f)){\in}\mathbb{N}$$

Again, let us use the same simulation technique as before to prove that in any context C with no occurrence of $\boldsymbol{a}$, if $C[\mathtt{force}(f)]\mapsto^*k$ then $C[\mathtt{bound}(b,f,\boldsymbol{a})]\mapsto^*k$. We prove that by induction on the length of the reduction $C[\mathtt{force}(f)]\mapsto^*k$. For that we prove that if $C[\mathtt{force}(f)]\mapsto u$ such that u computes to a canonical expression, and all the numbers occurring in $C[\mathtt{force}(f)]$ are strictly less than b, then there exists a context C' such that $u\mapsto^*C'[\mathtt{force}(f)]$ and $C[\mathtt{bound}(b,f,\boldsymbol{a})]\mapsto^*C'[\mathtt{bound}(b,f,\boldsymbol{a})]$.

Using this result, we get that $F(\mathtt{bound}(b,f,\boldsymbol{a}))\mapsto^*k$, from which we deduce that $\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(b,f,\boldsymbol{a}))\mapsto^*k$, and finally $\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(b,f,\boldsymbol{a}))=_{\mathbb{N}}F(\mathtt{force}(f))$.

4.8 2nd Condition

The second property we prove about the function `M` defined above in Sec. 4.4 is that for all f in $\mathcal{B}$ and n in $\mathbb{N}$, if $\mathtt{M}(F)\ n\ f$ computes to a number then $\mathtt{M}(F)\ n\ f=_{\mathbb{N}}F(f)$. In order to implement our search function to realize $\mathtt{SCP}_{\downarrow}$, we need to return the smallest n, say m, such that $\mathtt{M}(F)\ n\ f$ computes to a number. However, if $\mathtt{M}(F)$ could return different answers for different n's, we would not know whether $\mathtt{M}(F)\ m\ f$ returns $F(f)$ or some other value.

Let us prove that if $\mathtt{M}(F)\ n\ f\sim k$ for some $k\in\mathbb{N}$ then $F(f)\sim k$. As before, we can assume that $\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(n,f,\boldsymbol{a}))\sim k$, for some $\boldsymbol{a}$ such that $\boldsymbol{a}\#F$ and $\boldsymbol{a}\#f$. By typing we get that $F(f)$ computes to a natural number k'. Because $\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(n,f,\boldsymbol{a}))$ computes to a canonical form (the natural number k), we deduce that $F(\mathtt{bound}(n,f,\boldsymbol{a}))$ also computes to a canonical form. This canonical form is either (1) an exception or (2) a value.

(1) If $F(\mathtt{bound}(n,f,\boldsymbol{a}))$ computes to an exception then we get a contradiction: either the term computes to $\mathtt{exc}_{\boldsymbol{a}}$ and then we obtain that $\mathtt{try}_{\boldsymbol{a}}\ F(\mathtt{bound}(n,f,\boldsymbol{a}))\mapsto^*\star$ and $\star\neq k$; or it

computes to an exception e with some other name than $\boldsymbol{a}$ and then $\texttt{try}_{\boldsymbol{a}}\ F(\texttt{bound}(n,f,\boldsymbol{a})) \mapsto^* e$ and $e \neq k$. In both cases we get a contradiction.

(2) We now assume that $F(\texttt{bound}(n,f,\boldsymbol{a}))$ computes to a value. If so, it has to compute to k. We now prove that $k = k'$. As before, because $F(f) \equiv F(\texttt{force}(f)) \in \mathbb{N}$, we get that $F(\texttt{force}(f)) \mapsto^* k'$. The rest of this proof closely follows the one in Sec. 4.7. We prove that in any context C with no occurrence of $\boldsymbol{a}$, if $C[\texttt{force}(f)]$ computes to the natural number k' then $C[\texttt{bound}(n,f,\boldsymbol{a})]$ computes to either k' or $\texttt{exc}_{\boldsymbol{a}}$. We prove that by induction on the length of the reduction $C[\texttt{force}(f)] \mapsto^* k'$. For that we prove that if $C[\texttt{force}(f)] \mapsto u$ such that u computes to a canonical expression then there exists a context C' such that $u \mapsto^* C'[\texttt{force}(f)]$ and $C[\texttt{bound}(b,f,\boldsymbol{a})] \mapsto^* C'[\texttt{bound}(b,f,\boldsymbol{a})]$ or $C[\texttt{bound}(b,f,\boldsymbol{a})] \mapsto^* \texttt{exc}_{\boldsymbol{a}}$. We get that either: (1) $F(\texttt{bound}(b,f,\boldsymbol{a})) \mapsto^* k'$ and therefore $k = k'$; or (2) $F(\texttt{bound}(b,f,\boldsymbol{a})) \mapsto^* \texttt{exc}_{\boldsymbol{a}}$ and we get a contradiction because $k \neq \texttt{exc}_{\boldsymbol{a}}$.

4.9 Nuprl's Strong Continuity Inference Rule

Using the fact that SCPT (defined at the beginning of Sec. 4) is true in Nuprl's meta-theory, we proved that the following inference rule, called [StrongContinuity], is true w.r.t. Allen's PER semantics (for further details regarding this proof conducted in our implementation of Nuprl in Coq, the interested reader is invited to look at https://github.com/vrahli/NuprlInCoq/blob/master/continuity/continuity_roadmap.v):

$$\frac{H \vdash F \in (\mathbb{N} \to T) \to \mathbb{N} \qquad H \vdash \downarrow T \qquad H \vdash T \sqsubseteq \mathbb{N}}{H \vdash \texttt{M}(F) \in \texttt{SCPF}(F)}$$

Using this inference rule, we proved a version of SCPT in Nuprl, where the first (outer) existential quantifier is $\lfloor$-squashed and the second (inner) one is not squashed (this lemma can be accessed by clicking the following hyperlink: strong-continuity2-no-inner-squash).[6] We get rid of the second squash operator using the usual unbounded search μ operator. As expected the extract of that lemma is (we use colored parentheses for visual convenience):

$$\lambda F.\langle \texttt{M'}(F), \lambda f.\langle \mu(\lambda n.\texttt{isl}(\texttt{test'}(F,n,f))), \langle \star, \lambda m.\lambda i.\star \rangle \rangle \rangle$$

where

$$\texttt{test'}(F,n,f) = \texttt{let}\ x := \texttt{test}(F,n,f)\ \texttt{in}\ \texttt{ifint}(x, \texttt{inl}(x), \texttt{inr}(\star))$$

$$\texttt{M'}(F) = \lambda n.\lambda f.\texttt{test'}(F,n,f)$$

$$\mu(f) = \texttt{fix}\left(\begin{array}{l}\lambda F.\lambda n.\ \texttt{if}\ f(n)\ \texttt{then}\ n \\ \qquad\qquad \texttt{else let}\ m := n+1\ \texttt{in}\ F(m)\end{array}\right)\ 0$$

We then derived a version of SCP where, as mentioned in the introduction, the first (outer) $\boldsymbol{\Sigma}$ is $\lfloor \boldsymbol{\Sigma}$ and the second (inner) one is $\boldsymbol{\Sigma}$ (see/click Nuprl lemma strong-continuity2-no-inner-squash-unique). Therefore, because these versions of SCP are equivalent of $\texttt{SCP}_{\lfloor}$, we also refer to them as $\texttt{SCP}_{\lfloor}$.

5. Relations Between WCP and SCP

As mentioned in Sec. 1, Bridges and Richman [21, pp.119] state that SCP is equivalent to WCP plus some form of the axiom of choice—some version of $\text{AC}_{1,0}$. As we saw above the existential quantifiers in these statements have to be truncated using $\lfloor$ (see Escardó and Xu [45]). Therefore, for that equivalence to be true, we probably need the $\lfloor$-truncated version of $\text{AC}_{1,0}$, which is true in Nuprl as discussed below in Sec. 5.3. Therefore, we only need to prove that $\texttt{SCP}_{\lfloor}$ and $\texttt{WCP}_{\lfloor}$ are equivalent. We prove below that $\texttt{WCP}_{\lfloor}$ is a trivial consequence of $\texttt{SCP}_{\lfloor}$, and that $\texttt{SCP}_{\lfloor}$ is a consequence of $\texttt{WCP}_{\lfloor}$ using the same "trick" as the one used by Bridges and Richman to prove that UCP follows from the Fan Theorem and WCP [21, pp.113] (see Sec. 6.1 below on uniform continuity).

5.1 $\texttt{SCP}_{\lfloor}$ Implies $\texttt{WCP}_{\lfloor}$

Let us sketch the proof that $\texttt{SCP}_{\lfloor} \to \texttt{WCP}_{\lfloor}$. For convenience, we will write $\mathbb{N}_{\mathtt{U}}$ for $\mathbb{N}+\texttt{Unit}$. Let $F \in \mathcal{B} \to \mathbb{N}$ and $f \in \mathcal{B}$. We prove the formula $C = \lfloor \boldsymbol{\Sigma} n{:}\mathbb{N}.\ \boldsymbol{\Pi} g{:}\mathcal{B}.f =_{\mathbb{N}^{\mathbb{N}_n}} g \to F(f) =_{\mathbb{N}} F(g)$. From $\texttt{SCP}_{\lfloor}$, we get a $M \in \boldsymbol{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_{\mathtt{U}}$ (we can unsquash $\texttt{SCP}_{\lfloor}$'s outer $\boldsymbol{\Sigma}$ because our conclusion C is squashed) and a function

$$A \in \boldsymbol{\Pi} f{:}\mathcal{B}.\boldsymbol{\Sigma} n{:}\mathbb{N}.\quad M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f)) \\ \wedge\ \boldsymbol{\Pi} m{:}\mathbb{N}.\texttt{isl}(M\ m\ f) \to m =_{\mathbb{N}} n$$

By applying A to f we get a $n \in \mathbb{N}$ such that:

- $M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f))$
- and $B \in \boldsymbol{\Pi} m{:}\mathbb{N}.\texttt{isl}(M\ m\ f) \to m =_{\mathbb{N}} n$.

We unsquash and instantiate with n our conclusion C, and we now get to assume that there is a $g \in \mathcal{B}$ such that $f =_{\mathbb{N}^{\mathbb{N}_n}} g$. It remains to prove that $F(f) =_{\mathbb{N}} F(g)$. By applying A to g we get a $n' \in \mathbb{N}$ such that:

- $M\ n'\ g =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(g))$
- and $B' \in \boldsymbol{\Pi} m{:}\mathbb{N}.\texttt{isl}(M\ m\ g) \to m =_{\mathbb{N}} n'$.

Because $f =_{\mathbb{N}^{\mathbb{N}_n}} g$, we get that $M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} M\ n\ g$. Because $M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f))$, we get $\texttt{isl}(M\ n\ f)$ and therefore also $\texttt{isl}(M\ n\ g)$. Then, by applying B' to n we get $n =_{\mathbb{N}} n'$. Therefore, $\texttt{inl}(F(f)) =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(g))$, and finally we get that $F(f) =_{\mathbb{N}} F(g)$.

5.2 $\texttt{WCP}_{\lfloor}$ Implies $\texttt{SCP}_{\lfloor}$

In this section we prove that skWCP implies $\texttt{SCP}_{\lfloor}$ (see Nuprl lemma weak-continuity-implies-strong1), where skWCP is the following "skolemized" version of $\texttt{WCP}_{\lfloor}$:

$$\texttt{skWCP} = \boldsymbol{\Pi} F{:}\mathcal{B} \to \mathbb{N}. \\ \lfloor \boldsymbol{\Sigma} M{:}\mathcal{B} \to \mathbb{N}. \\ \boldsymbol{\Pi} f,g{:}\mathcal{B}.(f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} g) \to (F(f) =_{\mathbb{N}} F(g))$$

It is easy to prove that skWCP and $\texttt{WCP}_{\lfloor}$ are equivalent using our proof that the $\lfloor$-truncated axiom of choice $\text{AC}_{1,\text{X}}$ discussed below in Sec. 5.3 is true (see Nuprl lemma axiom-choice-1X-quot).

Let us assume skWCP and let $F \in \mathcal{B} \to \mathbb{N}$. We have to prove the following formula C:

$$\lfloor \boldsymbol{\Sigma} M{:}\boldsymbol{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \to \mathbb{N}_{\mathtt{U}}. \\ \boldsymbol{\Pi} f{:}\mathcal{B}.\quad \boldsymbol{\Sigma} n{:}\mathbb{N}.M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f)) \\ \wedge\ \boldsymbol{\Pi} n{:}\mathbb{N}.\texttt{isl}(M\ m\ f) \to M\ n\ f =_{\mathbb{N}_{\mathtt{U}}} \texttt{inl}(F(f))$$

Instantiating skWCP with F we get (because our conclusion C is $\lfloor$-truncated, we can unsquash our hypothesis):

- a $M \in \mathcal{B} \to \mathbb{N}$ (F' modulus of continuity)
- and a $G \in \boldsymbol{\Pi} f,g{:}\mathcal{B}.(f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} g) \to (F(f) =_{\mathbb{N}} F(g))$

Bridges and Richman's trick is to also use the modulus of continuity of M. Therefore, instantiating skWCP with M we get:

- a $X \in \mathcal{B} \to \mathbb{N}$ (M's modulus of continuity)
- and a $K \in \boldsymbol{\Pi} f,g{:}\mathcal{B}.(f =_{\mathbb{N}_{X(f)} \to \mathbb{N}} g) \to (M(f) =_{\mathbb{N}} M(g))$

Let us now unsquash our conclusion C and instantiate it with

$$B = \lambda n.\lambda a.\texttt{if}\ M(a_{n,0}) \leq n\ \texttt{then}\ \texttt{inl}(F(a_{n,0}))\ \texttt{else}\ \texttt{inr}(\star)$$

[6] Alternatively, the reader can search for the lemma with that name available here: http://www.nuprl.org/LibrarySnapshots/Published/Version1/Standard/continuity/index.html, and similarly for the other Nuprl lemmas mentioned below and highlighted in green.

where $a_{n,k} = \lambda x.\texttt{if } x{<}n \texttt{ then } a(x) \texttt{ else } k$ (this is the infinite sequence consisting of the first n values of a followed by k's—$a_{n,0}$ is sometimes denoted $\overline{a,n}$, e.g., in [14, 41]). If $a \in \mathbb{N}^{\mathbb{N}_n}$ and $k \in \mathbb{N}$ then $a_{n,k} \in \mathbb{N} \to \mathbb{N}$. We now have to prove that assuming that $f \in \mathcal{B}$ then:

$$\mathbf{\Sigma} n{:}\mathbb{N}.B\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f)) \quad (4)$$

$$\mathbf{\Pi} n{:}\mathbb{N}.\texttt{isl}(B\ n\ f) \to (B\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))) \quad (5)$$

Equality 5 follows from G. We now prove 4 by instantiating it with $m = \texttt{max}(M(f), X(f))$. We have to prove $B\ m\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$, i.e.,

$$\texttt{if } M(a_{m,0}) \leq m \texttt{ then inl}(F(a_{m,0})) \texttt{ else inr}(\star) \quad (6)$$
$$=_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$$

Because $f =_{\mathbb{N}_{M(f)} \to \mathbb{N}} a_{m,0}$, then using G we obtain: $F(f) =_{\mathbb{N}} F(a_{m,0})$. Therefore, to prove equality 6, it remains to prove that its conditional is true, i.e., $M(a_{m,0}) \leq m = \texttt{max}(M(f), X(f))$. If we instantiate K with f and $a_{m,0}$, we have to prove $f =_{\mathbb{N}_{X(f)} \to \mathbb{N}} a_{m,0}$, which is true by definition of m, and get to assume $M(f) =_{\mathbb{N}} M(a_{m,0})$ which gives us that $M(a_{m,0}) \leq m$.

5.3 Axiom of Choice

The following axiom of choice is usually trivial in constructive type theories such as Nuprl when $\underline{\mathbf{\Sigma}}$ is $\mathbf{\Sigma}$ (where A and B are types):

$$AC = \mathbf{\Pi} a{:}A.\underline{\mathbf{\Sigma}} b{:}B.\ P\ a\ b\ \Rightarrow\ \underline{\mathbf{\Sigma}} f{:}B^A.\ \mathbf{\Pi} a{:}A.P\ a\ f(a)$$

It follows from the usual rules of the universal and existential quantifiers. We can prove that these rules are true in our predicative Coq model [9, 10] without assuming any axiom. In that predicative model we can model n Nuprl universes using $n+1$ Coq universes. However, in our impredicative model we have to assume some axiom of choice, namely FunctionalChoice_on (see http://coq.inria.fr/cocorico/CoqAndAxioms), to prove some of these rules.

However, the non-squashed version of AC is not always enough because as we saw above existential quantifiers cannot always be interpreted as $\mathbf{\Sigma}$ but sometimes as truncated $\mathbf{\Sigma}$'s. Therefore, we sometimes need instances of AC where $\underline{\mathbf{\Sigma}}$ is either $\downarrow\mathbf{\Sigma}$ or $\downarrow\mathbf{\Sigma}$. In that case it is not obvious anymore which instances of AC are consistent or provable in Nuprl.

Some versions of AC for particular choices of types A and B are of particular interest. One can often find in the literature the name $\text{AC}_{n,m}$, where $n, m \in \{0, 1\}$ [92, pp.238]: $n = 0$ means that $A = \mathbb{N}$ and $n = 1$ means that $A = \mathcal{B}$; similarity $m = 0$ means that $B = \mathbb{N}$ and $m = 1$ means that $B = \mathcal{B}$.

Using a technique similar to the one discussed in [82], we proved the $\downarrow$-squashed version of $\text{AC}_{0,0}$, where $\underline{\mathbf{\Sigma}}$ is $\downarrow\mathbf{\Sigma}$, once again conducting the proof first in the meta-theory, and then reflecting the meta-theoretical result in the Nuprl theory as an inference rule: see lemma rule_AC00_true in https://github.com/vrahli/NuprlInCoq/blob/master/axiom_choice/axiom_choice.v. We also proved directly in Nuprl the $\downarrow$-squashed versions of AC, where $\underline{\mathbf{\Sigma}}$ is $\downarrow\mathbf{\Sigma}$, namely $\text{AC}_{0,\text{X}}$ (see Nuprl lemma axiom-choice-0X-quot) and $\text{AC}_{1,\text{X}}$ (see Nuprl lemma axiom-choice-1X-quot)—X here indicates that the type B above could be anything. These two lemmas are instances of the more general Nuprl lemma: axiom-choice-quot.

6. Applications

Using $\texttt{SCP}_\downarrow$ we proved in Nuprl a $\downarrow$-truncated version of UCP (see Sec. 1) from the fan theorem, and then a fully unsquashed version of this principle using Escardó and Xu's method [45] (see Sec. 6.1). We write $\texttt{UCP}_\downarrow$ for the version of UCP where $\underline{\mathbf{\Sigma}}$ is $\downarrow\mathbf{\Sigma}$. Using $\texttt{UCP}_\downarrow$ we then proved that real functions defined on the unit interval are uniformly continuous (see Sec. 6.2).

We have recently proved that Bar Induction on Decidable bars (BID) is consistent with Nuprl using our Coq model of Nuprl [82], and this for free choice sequences of natural numbers. Following Kleene, given that $\texttt{SCP}_\downarrow$ is true we can now prove Bar Induction on Monotone bars (BIM) [58, pp.78] (see also Dummett's Thm 3.8 [40, pp.64]): see Nuprl lemma monotone-bar-induction1.

We have also recently used exceptions to implement the constructive content of the completeness result of intuitionistic first-order logic proved in [29]. As in the present paper, exceptions are used to probe how a computation uses its arguments. Given a uniform evidence for a proposition, we construct a proof of that proposition by using this probing mechanism to determine the next step of the proof.

6.1 Uniform Continuity

6.1.1 $\texttt{UCP}_\downarrow$ Follows From FT and $\texttt{SCP}_\downarrow$.

Using BID we prove that the Fan Theorem (FT) is true: see Nuprl lemma fan_theorem. We then derive $\texttt{UCP}_\downarrow$ from FT and $\texttt{SCP}_\downarrow$: see Nuprl lemma strong-continuity2-implies-uniform-continuity. Let us sketch that proof. The version of FT that we have proved in Nuprl is (if X is a bar and is decidable then it is uniform):

$$\begin{aligned}\texttt{FT} = \ & \mathbf{\Pi} X{:}(\mathbf{\Pi} n{:}\mathbb{N}.2^{\mathbb{N}_n} \to \mathbb{P}).\\ & \mathbf{\Pi} f{:}\mathcal{C}.{\downarrow}\mathbf{\Sigma} n{:}\mathbb{N}.X\ n\ f\\ & \to\ \mathbf{\Pi} n{:}\mathbb{N}.\mathbf{\Pi} f{:}2^{\mathbb{N}_n}.\texttt{Dec}(X\ n\ f)\\ & \to\ \mathbf{\Sigma} k{:}\mathbb{N}.\mathbf{\Pi} f{:}\mathcal{C}.\mathbf{\Sigma} n{:}\mathbb{N}_k.X\ n\ f\end{aligned}$$

We also use the following corollary of $\texttt{SCP}_\downarrow$ for functions on the Cantor space instead of the Baire space:

$$\begin{aligned}&\texttt{SCPB}\\ &= \mathbf{\Pi} F{:}\mathcal{C} \to \mathbb{N}.\\ &\quad {\downarrow}\mathbf{\Sigma} M{:}(\mathbf{\Pi} n{:}\mathbb{N}.2^{\mathbb{N}_n} \to \mathbb{N}_\mathbb{U}).\\ &\quad\quad \mathbf{\Pi} f{:}\mathcal{C}.\\ &\quad\quad\quad \mathbf{\Sigma} n{:}\mathbb{N}.M\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))\\ &\quad\quad\quad \wedge\ \mathbf{\Pi} n{:}\mathbb{N}.\texttt{isl}(M\ n\ f) \to M\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))\end{aligned}$$

Let us start proving $\texttt{UCP}_\downarrow$. Let F be in $\mathcal{C} \to \mathbb{N}$. We have to prove

$${\downarrow}\mathbf{\Sigma} n{:}\mathbb{N}.\ \mathbf{\Pi} f, g{:}\mathcal{C}.f =_{2^{\mathbb{N}_n}} g \to F(f) =_{\mathbb{N}} F(g) \quad (7)$$

We start by instantiating SCPB with F and we unsquash the resulting formula (which we can do because our conclusion is squashed), i.e., we get to assume:

- $M \in \mathbf{\Pi} n{:}\mathbb{N}.2^{\mathbb{N}_n} \to \mathbb{N}_\mathbb{U}$ and
- $G \in \mathbf{\Pi} f{:}\mathcal{C}.\quad \mathbf{\Sigma} n{:}\mathbb{N}.M\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$
  $\wedge\ \mathbf{\Pi} n{:}\mathbb{N}.\texttt{isl}(M\ n\ f) \to M\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$

We now instantiate FT using $X = \lambda n.\lambda f.\texttt{isl}(M\ n\ f)$. We now have to prove (1) $\mathbf{\Pi} f{:}\mathcal{C}.{\downarrow}\mathbf{\Sigma} n{:}\mathbb{N}.\texttt{isl}(M\ n\ f)$, which follows from G; and (2) $\mathbf{\Pi} n{:}\mathbb{N}.\mathbf{\Pi} f{:}2^{\mathbb{N}_n}.\texttt{Dec}(\texttt{isl}(M\ n\ f))$, which is trivial; and we get a $k \in \mathbb{N}$ and $A \in \mathbf{\Pi} f{:}\mathcal{C}.\mathbf{\Sigma} n{:}\mathbb{N}_k.\texttt{isl}(M\ n\ f)$. We unsquash and instantiate our conclusion 7 using $k-1$. We have to prove that $F(f) =_{\mathbb{N}} F(g)$ assuming that $f =_{2^{\mathbb{N}_k}} g$ for f and g in $\mathcal{C}$. From G we get:

- $G(f) \in \mathbf{\Pi} n{:}\mathbb{N}.\texttt{isl}(M\ n\ f) \to M\ n\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$
- $G(g) \in \mathbf{\Pi} n{:}\mathbb{N}.\texttt{isl}(M\ n\ g) \to M\ n\ g =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(g))$

and from A (applying A to f) we get a $i \in \mathbb{N}_k$ and that $\texttt{isl}(M\ i\ f)$. Therefore, because $f =_{2^{\mathbb{N}_k}} g$, we get $M\ i\ f =_{\mathbb{N}_\mathbb{U}} M\ i\ g$ and $\texttt{isl}(M\ i\ g)$. Which means that (from $G(f)$ and $G(g)$):

- $M\ i\ f =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(f))$
- $M\ i\ g =_{\mathbb{N}_\mathbb{U}} \texttt{inl}(F(g))$

We conclude that $F(f) =_{\mathbb{N}} F(g)$.

6.1.2 $\texttt{UCP}_\downarrow$ Follows From FT and skWCP.

Following Bridges and Richman's proof of their Theorem 3.2 [21, pp.113], the following Nuprl lemma proves that $\texttt{UCP}_\downarrow$ follows

from FT and skWCP: fan+weak-continuity-implies-uniform-continuity (as mentioned in Sec. 5, skWCP and $\texttt{WCP}_{\downarrow}$ are equivalent). Their proof is slightly more involved than the one presented above in Sec. 6.1.1 and uses the "trick" of building a bar that uses both the skolemized modulus of continuity M of type $\mathcal{C} \to \mathbb{N}$ of a functional F of type $\mathcal{C} \to \mathbb{N}$ and the (skolemized) modulus of continuity of M. As mentioned above skWCP is a trivial consequence of $\texttt{SCP}_{\downarrow}$: see Nuprl lemma strong-continuity2-implies-weak-skolem-cantor-nat.

6.1.3 Unsquashed UCP Follows From $\texttt{UCP}_{\downarrow}$.

We can then get rid of the truncation operator $\downarrow$ in $\texttt{UCP}_{\downarrow}$ following exactly Escardó and Xu's proof [45, Sec.4]: see Nuprl lemma strong-continuity2-implies-uniform-continuity2. Their proof consists in proving that (1) the existence of a uniform modulus of continuity is equivalent to (2) the existence of the smallest uniform modulus of continuity. Because (2) is a proposition in HoTT's sense [93], we can "untruncate" it. Their proof goes in three steps: Nuprl lemma uniform-continuity-pi-dec corresponds to their Lemma 4; Nuprl lemma prop-truncation-implies corresponds to their Lemma 5; and Nuprl lemma uniform-continuity-pi-pi-prop2 corresponds to their Lemma 6.

6.2 Brouwer's Theorem on Uniform Continuity

In Nuprl, a real number $\alpha : \mathbb{R}$ is a regular sequence of integers. This means that $\alpha : \mathbb{N}^+ \to \mathbb{Z}$ and $\forall n, m. |n * \alpha(m) - m * \alpha(n)| \leq 2(n+m)$. This differs from, but is equivalent to, Bishop's definition of real numbers as regular sequences of rationals [17]. Two regular sequences α and β represent the same real number if $\forall n.\ |\alpha(n) - \beta(n)| \leq 4$, and this is an equivalence relation, $\alpha =_r \beta$, on regular sequences. If $\alpha(n) + 4 < \beta(n)$ for some n, then $\alpha < \beta$, and $\alpha \# \beta$ (α is apart from β) if $\alpha < \beta \vee \beta < \alpha$. If $\forall n. \alpha(n) \leq \beta(n) + 4$, then $\alpha \leq \beta$.

The closed interval $[\alpha, \beta]$ is the type $\{x : \mathbb{R} \mid \alpha \leq x \leq \beta\}$. Bishop calls a member f of the type $[\alpha, \beta] \to \mathbb{R}$ an *operation* on the interval $[\alpha, \beta]$, and reserves the word *function* for those operations that satisfy

$$\text{FUN}(f, \alpha, \beta) = \forall x, y : [\alpha, \beta].\ x =_r y \Rightarrow f(x) =_r f(y)$$

A stronger condition—called strong extensionality in Coq's CoRN library [61]—is

$$\text{SFUN}(f, \alpha, \beta) = \forall x, y : [\alpha, \beta].\ f(x) \# f(y) \Rightarrow x \# y$$

An operation is uniformly continuous on $[\alpha, \beta]$ if

$$\begin{array}{l}\text{CONT}(f, \alpha, \beta) \\ = \forall \epsilon > 0. \\ \quad \exists \delta > 0.\ \forall x, y : [\alpha, \beta].\ |x - y| \leq \delta \to |f(x) - f(y)| \leq \epsilon\end{array}$$

(The Nuprl lemmas mentioned below are available at the following addess: http://www.nuprl.org/LibrarySnapshots/Published/Version1/Standard2/reals/index.html.) Using the fact from Sec. 6.1 that functionals of type $\mathcal{C} \to \mathbb{Z}$ are uniformly continuous, we proved in Nuprl that for *proper* intervals $[\alpha, \beta]$ (where $\alpha < \beta$), we have (see Nuprl lemma real-continuity4):

$$\text{CONT}(f, \alpha, \beta) \Leftrightarrow \text{FUN}(f, \alpha, \beta)$$

In the proof, we construct the usual map from $\mathcal{C}$ onto $[\alpha, \beta]$, using a tree of nested, decreasing intervals. However, we can not show that this is an onto map without using the condition $\alpha < \beta$. Using the fact that we can decide whether a functional of type $\mathcal{C} \to \mathbb{Z}$ is constant, we could extend the proof to the case of intervals that are not necessarily proper—for which only $\alpha \leq \beta$—to show that (see Nuprl lemma real-continuity3):

$$\text{CONT}(f, \alpha, \beta) \Leftrightarrow \text{SFUN}(f, \alpha, \beta)$$

Thus, for Bishop's definition of real function, it is correct to say that all functions on the unit interval $[0, 1]$ are uniformly continuous (Brouwer's theorem). But it is not correct to say that functions are uniformly continuous on all closed intervals $[\alpha, \beta]$—only on proper closed intervals—unless the strongly extensional definition of real function is used. The two definitions are equivalent only when Markov's principle holds [17].

7. Related Work on Nominal Systems

Nominal systems. There has been a tremendous amount of work on nominal approaches to logic and programming starting from Gabbay and Pitts' work on using Fraenkel-Mostowski's permutation model of set theory to formally reason about abstract syntax in the presence of α-equivalence and variable binding [47]. This work then led to the design of the so-called Nominal Logic [76], which provides primitives and axioms to reason about names, name-swapping, freshness, and name-binding. These ideas were then later used and implemented in programming languages and type theories [18, 22–25, 38, 46, 75, 77, 78, 80, 81, 87–89, 98] (to cite only a few). We know describe some of these systems.

FreshML. For example, FreshML [78, 89] is an extension of ML with constructs for declaring and manipulating data with binding structure that provide support for object-level α-equivalence, such as constructs for binding names, declaring new types of bindable names, and generating fresh names. Nuprl does not yet have such a name-abstraction construct. Also, our paper does not try to tackle the issue of reasoning about α-equivalence classes of terms using names. This provides an alternative approach to, e.g., using de Bruijn indices or HOAS in order to deal with names and binders. These ideas were then also ported to OCaml [88]. Following this line of work, Pure FreshML [80] is a pure (in the sense that name generation is not an observable side effect) version of FreshML [89] that ensures fresh atoms do not escape their scopes.

Nominal type theories. Schopp and Stark [86, 87] developed a *bunched* dependent type theory for programming and reasoning with names, based on a categorical axiomatization of names, and taking freshness as the central primitive instead of swapping. Bunches are typing contexts that have a tree-like shape instead of a list-like shape, where branching is used to model the disjointness of names spaces. In their theory, α-equivalence classes can be either modeled as "fresh functions" or as pairs, which are members of "non-standard fresh" $\mathbf{\Pi}^*$ and $\mathbf{\Sigma}^*$ types. It turns out that these types are isomorphic when indexed by names, giving rise to a *hidden-name* type constructor $\mathbf{H}$ which can either be interpreted as a sum or a product, and which corresponds to Gabbay and Pitts freshness quantifier $\mathbf{И}$ [47]. In our paper, we only focus on computational aspects of freshness.

Cheney designed SNTT [22], which is a nominal simply-typed λ-calculus with names as well as name-abstraction and name-concretion operators (but no name-generation operator such as $\boldsymbol{\nu}$). SNTT contexts are expressive enough so that one can state the freshness constraint on name-concretions. It is also designed with decidable typechecking in mind. Cheney extended SNTT to a dependent type theory, called $\lambda^{\mathbf{\Pi И}}$ [23], with dependent products ($\mathbf{\Pi}$) and dependent name-abstraction types ($\mathbf{И}$). As for SNTT, one of his main focus was to provide a strongly normalizing theory with decidable type checking.

Westbrook's CNIC calculus (the Calculus of Nominal Inductive Constructions) [97, 98] can also be seen as an extension of SNTT with inductive constructions, or similarly as an extension of CIC [35] with nominal features such as name abstraction and concretion operators, and pattern matching operators for names and name abstractions.

Pitts' Nominal System T [77] extends System T with nominal features such as a fresh operator $\boldsymbol{\nu}$ à la Odersky and a name-swapping operator. As opposed to the systems mentioned above,

this system has ordinary non-bunched contexts. FreshMLTT [75] is a dependent type theory that has name-abstraction and name-concretion operators, as well as a name-swapping operator and a fresh operator $\boldsymbol{\nu}$ à la Odersky, which allow them to derive expressive name-concretion rules.

8. Conclusion and Future Work

This paper provides "mostly" computational proofs of two Brouwerian continuity principles that use (1) diverging terms to prove that the modulus of continuity of a function on the Baire space exists in the meta-theory (Sec. 3), and (2) named exceptions to exhibit it in the theory (Sec. 4). We proved that all functions of type $T^{\mathbb{N}} \to \mathbb{N}$ are continuous, where T is a subtype of $\mathbb{N}$. It is not clear how to adapt our proof for other types than subtypes of $\mathbb{N}$. This is left for future work.

In Sec. 4.8 we used the fact that the exception $\mathtt{exc}_{\boldsymbol{a}}$ cannot be caught by F if $\boldsymbol{a}\#F$. This would not longer be true if our computation system was non-deterministic or if we allowed parallel computations. For example, let $t_1 \mid\mid t_2$ be an operator that dovetails the computations of t_1 and t_2. If t_1 computes to $\mathtt{exc}_{\boldsymbol{a}}$ then this exception might get "caught" if t_2 computes to a canonical expression "before" t_1. Once we add non-determinism to Nuprl, we might be able to use non-deterministic computations to compute the modulus of continuity of functions in a similar fashion as done by Coquand and Jaber [34]. This is left for future work.

Finally, many more inference rules can be derived (and verified in our Coq model) from the definitions of our new computations and types than the ones discussed in Sec. 4. Investigating these rules is left for future work.

Acknowledgements

A. Sequents and Rules

In Nuprl, one reasons about types using a sequent calculus, which is a collection of rules that captures many properties of Nuprl's computation and type systems. For example, for each type we have introduction and elimination rules. This calculus can be extended as required by adding more types and/or rules. This section presents the syntax and semantics of Nuprl's sequents and rules. See [9, 10] for more details. We have already verified a large number of Nuprl's inference rules. Our formalization of Nuprl in Coq provides a safe way to add new inference rules to Nuprl by mechanizing their semantics, and allowing one to formally prove their validity, which is a difficult task without the help of a proof assistant. Howe [55] writes: "Because of this complexity, many of the Nuprl rules have not been completely verified, and there is a strong barrier to extending and modifying the theory".

Syntax of Sequents and Rules. Sequents are of the form $h_1, \ldots, h_n \vdash T \lfloor \textbf{ext } t \rfloor$, where t is the *extract/evidence* of T, and where an hypothesis h is either of the form $x : A$ (non-hidden) or of the form $[x : A]$ (hidden). Such a sequent states, among other things, that T is a type and t is a member of T. We write $H \vdash T$ for $H \vdash T \lfloor \textbf{ext } \star \rfloor$ or whenever the extract is irrelevant. A rule is a pair of a sequent and a list of sequents, which we write either as (where *name* is the name of the rule):

$$(S_1 \wedge \cdots \wedge S_n) \Rightarrow S$$

or

$$\frac{S_1 \quad \cdots \quad S_n}{S} \ \textit{name}$$

or

$$\begin{array}{l} S \\ \quad \text{BY } \textit{name} \\ \quad S_1 \\ \quad \vdots \\ \quad S_n \end{array}$$

Hidden hypotheses. To understand the necessity of hidden hypotheses, let us consider the following intersection introduction rule:

$$H, [x : A] \vdash B[x] \lfloor \textbf{ext } e \rfloor \ \wedge \ H \vdash A = A \in \mathbb{U}_i \ \Rightarrow \ H \vdash \cap a{:}A.B[a] \lfloor \textbf{ext } e \rfloor$$

This rule says that to prove that $\cap a{:}A.B[a]$ is true with extract e, one has to prove that $B[x]$ is true with extract e, assuming that x is of type A. The meaning of intersection types requires that the extract e be the same for all values of A, and is therefore called the *uniform evidence* of $\cap a{:}A.B[a]$. The fact that x is hidden means that it cannot occur free in e (but can occur free in B). The same mechanism is required to state the rules for, e.g., subset types or quotient types.

Hidden hypotheses can be unhidden when proving conclusions that do not have any computational content such as equalities. Therefore, the following rule is valid according to Allen's PER semantics explained below:

$$\begin{array}{l} H, [x : T], J \vdash a =_C b \\ \quad \text{BY } \texttt{[Unsquash]} \\ \quad H, x : T, J \vdash a =_C b \end{array}$$

Digression on Intersection types. As a side note, non-dependent intersections of type families and dependent intersection types were studied by Kopylov [59] and added to the MetaPRL [52] (a cousin of Nuprl mostly developed by Hickey) and Nuprl systems (intersections of type families were added to Nuprl around 2000 [31]). Intersection types have recently been used by Constable and Bickford to

prove a completeness result of intuitionistic first-order logic [29]. Around the same time, Miquel [68–70] was also studying the addition of intersections of type families to a Curry-style version of the Calculus of Constructions. In Nuprl, we mostly use intersection types to avoid "noise" in our extracts, e.g., to avoid having type parameters in extracts that have no role in the computational content of the extracts, and are only used for typing purposes. We believe that intersection types are central in our theory and we proposed in [8] an alternative definition of Nuprl that relies on partial equivalence relation types and intersection types as the main logical universal quantifier.

Semantics of Sequents and Rules. Several definitions for the truth of sequents occur in the Nuprl literature [28, 37, 59]. Among these, Kopylov [59]'s definition was the simplest. Our definition in [9, 10] is a simplified version of Kopylov's definition, and we have proved in that all these definitions are equivalent [10, Sec. 5.1]. The semantics we present uses a notion of *pointwise functionality* [37, Sec. 4.2.1], which says that each type in a true sequent must respect the equalities of the types on which it depends. This is captured by formula 8 below for the hypotheses of a sequent, and by formula 9 for its conclusion. For the purpose of this discussion, let us ignore the possibility that some hypotheses can be hidden.

Let H be a list of hypotheses of the form $x_1 : T_1, \ldots, x_n : T_n$, let s_1 be a substitution of the form $(x_1 \mapsto t_1, \ldots, x_n \mapsto t_n)$, and let s_2 be a substitution of the form $(x_1 \mapsto u_1, \ldots, x_n \mapsto u_n)$.

Similarity. Similarity lifts the notion of equality in a type (i.e., the relation $\_\equiv\_\in\_$) to lists of hypotheses. We say that s_1 and s_2 are similar in H, and write $s_1 \equiv s_2 \in H$, if for all $i \in \{1, \ldots, n\}$, $t_i \equiv u_i \in T_i[x_1 \backslash t_1; \cdots; x_{i-1} \backslash t_{i-1}]$. Let $s \in H$ be $s \equiv s \in H$.

Equal Hypotheses. The following notion of equality lifts the notion of equality between types (i.e., the relation $\_\equiv\_$) to lists of hypotheses. We say that the hypotheses H are equal w.r.t. s_1 and s_2, and write $s_1(H) \equiv s_2(H)$, if for all $i \in \{1, \ldots, n\}$, $T_i[x_1 \backslash t_1; \cdots; x_{i-1} \backslash t_{i-1}] \equiv T_i[x_1 \backslash u_1; \cdots; x_{i-1} \backslash u_{i-1}]$.

Hypotheses Functionality. We say that the hypotheses H are pointwise functional w.r.t. the substitution s, and write $H @ s$ if

$$\forall s'.\ s \equiv s' \in H \Rightarrow s(H) \equiv s'(H) \tag{8}$$

Truth of Sequents. We say that a sequent of the form $H \vdash T\ \lfloor \textbf{ext}\ t \rfloor$ is true if

$$\forall s_1, s_2.\ s_1 \equiv s_2 \in H \wedge H @ s_1 \ \Rightarrow\ T[s_1] \equiv T[s_2] \wedge t[s_1] \equiv t[s_2] \in T[s_1] \tag{9}$$

In addition the free variables of t have to be non-hidden in H.

Validity of Rules. A rule of the form $(S_1 \wedge \cdots \wedge S_n) \Rightarrow S$ is valid if assuming that the sequents S_1, …, S_n are true then the sequent S is also true.

Consistency. Using our formalization of Nuprl in Coq, we have already verified a large number of Nuprl's inference rules, including the usual introduction and elimination rules to reason about the core type system presented above in [9].

A Nuprl proof is a tree of sequents where each node corresponds to the application of a rule. Because we have proved that the above mentioned rules are correct, using the definition of the validity of a rule, and by induction on the size of the tree, this means that the sequent at the root of the tree is true w.r.t. Nuprl's PER semantics. Hence, a proof of False, for any meaningful definition of False, i.e., a type with an empty PER such as $0 = 1 \in \mathbb{Z}$, $0 \preceq 1$, or $\star \preceq \bot$ (this one says that $\bot$ converges), would mean that its PER is in fact non-empty, which leads to a contradiction.

Extensionality. Nuprl is both extensional in the sense that function extensionality is true by definition of $\mathbf{\Pi}$ types, and intensional in the sense that not all types with equal members (up to equality) are equal. This is also illustrated in Nogin's PhD thesis [72, pp.39]. For example, equality types have trivial content. Both $0 =_{\mathbb{Z}} 0$ and $1 =_{\mathbb{Z}} 1$ are inhabited by $\star$. These two types have equal members but they are not equal as types. As it was recently reminded to us by our colleague Evan Moran, this intensionality is necessary to validate sequents such as $h : x \in \mathbb{Z} \vdash \mathbb{Z}\ \lfloor \textbf{ext}\ x \rfloor$, where $h : x \in \mathbb{Z}$ is an hypothesis named h of type $x \in \mathbb{Z}$, and x is the *extract* of the sequent (i.e., the evidence that shows that $\mathbb{Z}$ is true, i.e., an inhabitant of that type). According to Nuprl's PER semantics (See [9, 10] for the definition of equality types) and under an extensional definition of equality types, because $2 =_{\mathbb{Z}} 2$ and $3 =_{\mathbb{Z}} 3$ would be equal types, then we would have to prove that $2 \equiv 3 \in \mathbb{Z}$.

B. `Top`, `Base`, $\preceq$, and $\simeq$

Some of the results mentioned in this section were presented in [83].

Note that $t_1 \preccurlyeq t_2$ is Howe's approximation (or simulation) metarelation while $t_1 \preceq t_2$ is a type. This type is formally defined as follows:

$$\begin{array}{l}\texttt{per\_approx}(\tau, T, T', \phi) = \\ \exists a, b, c, d. \\ \quad T \Downarrow a \preceq b \\ \quad \wedge\ T' \Downarrow c \preceq d \\ \quad \wedge\ (a \preccurlyeq b \iff c \preccurlyeq d) \\ \quad \wedge\ (\forall t, t'.\ t\ \phi\ t' \iff a \preccurlyeq b \wedge t \Downarrow \star \wedge t' \Downarrow \star)\end{array}$$

The relation `per_approx` expresses when two types T and T' are equal approximation types and defines the equality of ϕ of T. See [6, 9, 10, 37] for more details. In this definition τ is called a candidate type system. It is not used in this definition because approximation types do not have types as subterms. However it is used in, e.g., the definition of dependent products types to state, e.g., that for two dependent product types to be equal, their domains have to be equal (w.r.t. the candidate type system). Not that approximation types are extensional in the sense that all true approximation types are equal and all false approximation types are equal (third clause in `per_approx`'s definition).

Similarly, $t_1 \sim t_2$ is Howe's computational equivalence (or bisimulation) metarelation while $t_1 \simeq t_2$ is a type. This type is formally defined as follows:

$$\begin{array}{l}\texttt{per\_compeq}(\tau, T, T', \phi) = \\ \exists a, b, c, d. \\ \quad T \Downarrow a \simeq b \\ \quad \wedge\ T' \Downarrow c \simeq d \\ \quad \wedge\ (a \sim b \iff c \sim d) \\ \quad \wedge\ (\forall t, t'.\ t\ \phi\ t' \iff a \sim b \wedge t \Downarrow \star \wedge t' \Downarrow \star)\end{array}$$

`Base` is the type of all closed terms with $\sim$ as its equality. It is a primitive type. `Top` is the type of all closed terms with `True` as its equality. It is currently defined as follows: $\texttt{Top} = \cap x{:}\texttt{Void}.\texttt{Void}$. A more intuitive (equivalent) definition might be `Base//True`.

Here are a few rules we can prove about $\simeq$ and $\preceq$:

$H \vdash a \preceq a$
BY `[approx-refl]`

$H \vdash a \simeq a$
BY `[compeq-refl]`

$H \vdash a \simeq b$
BY `[compeq-base]`
$H \vdash a = b \in \texttt{Base}$

$H \vdash a\ b \simeq c\ d$
BY `[compeq-app-D]`
$H \vdash a \simeq c$
$H \vdash b \simeq d$

$H \vdash \lambda x.a \simeq \lambda x.b$
BY `[compeq-lam-D]`
$H, x : \texttt{Base} \vdash a \simeq b$

$H \vdash a \simeq b$
BY `[compeq-approx]`
$H \vdash a \preceq b$
$H \vdash b \preceq a$

It turns out we can prove that [approx-refl] is a valid rule because $\preceq$ is an extensional type. If it was not, we would not be able to prove the "functionality" of $a \preceq a$ in any context. We will freely use these rules below.

It turns out that when proving a proposition of the form $a \simeq b$ or of the form $a \preceq b$ in the context of an hypothesis $x : \texttt{Top}$, then we can always change this instance of Top into Base. Let us assume that we are proving a sequent of the form

$$H, x : \texttt{Top}, J \vdash a \simeq b$$

Because $a \simeq (\lambda x.a)\ x$ and $b \simeq (\lambda x.b)\ x$ are true in any context (using computation and [compeq-refl]), it is enough to prove

$$H, x : \texttt{Top}, J \vdash (\lambda x.a)\ x \simeq (\lambda x.b)\ x$$

Using [compeq-app-D], [compeq-refl], and [compeq-lam-D], it is enough to prove

$$H, x : \texttt{Top}, J, x' : \texttt{Base} \vdash a[x\backslash x'] \simeq b[x\backslash x']$$

which can easily be turned into

$$H, x : \texttt{Base}, J \vdash a \simeq b$$

C. Effect of Adding Exceptions on Nuprl's Inference Rules

Before adding exceptions to Nuprl's computation system, the following rule was key to reason about the approximation type $t_1 \preceq t_2$ (where $\texttt{halts}(t) = \star \preceq (\texttt{let}\ x := t\ \texttt{in}\ \star)$, and $\mathbb{P}$ is $\mathbb{U}_i$ for some level i):

$$\begin{array}{l} H \vdash t_1 \preceq t_2 \\ \quad \text{BY [convergence]} \\ \quad H, y : \texttt{halts}(t_1) \vdash t_1 \preceq t_2 \\ \quad H \vdash \texttt{halts}(t_1) \in \mathbb{P} \end{array}$$

Given our new definition of $\preccurlyeq$, this rule is not valid anymore. Now we also have to prove that $t_1 \preceq t_2$ is true assuming that t_1 is an exception. We can state that a term is an exception as follows: $\texttt{isexc}(t) = \texttt{exc}(\bot, \bot) \preceq t$. The [convergence] rule can now be stated as follows:

$$\begin{array}{l} H \vdash t_1 \preceq t_2 \\ \quad \text{BY [convergence]} \\ \quad H, y : \texttt{halts}(t_1) \vdash t_1 \preceq t_2 \\ \quad H, y : \texttt{isexc}(t_1) \vdash t_1 \preceq t_2 \\ \quad H \vdash \texttt{halts}(t_1) \in \mathbb{P} \\ \quad H \vdash \texttt{isexc}(t_1) \in \mathbb{P} \end{array}$$

Let us now discuss some implications of [convergence] having changed. Using this rule we used to be able to prove that for all $a, b \in \texttt{Top}$, $a + b \simeq b + a$. This is not true anymore because, e.g., if a raises an exception and b diverges then $a + b$ raises the exception while $b + a$ diverges. Also if a raises an exception e_1 and b raises an exception e_2 then $a + b$ raises e_1 while $b + a$ raises e_2. However, we can still prove that for all $a \in \mathbb{Z}$ and $b \in \texttt{Top}$, $a + b \simeq b + a$, and for all $a \in \texttt{Top}$ and $b \in \mathbb{Z}$, $a + b \simeq b + a$.

Let us sketch these proofs. For now, let a and b be unconstrained, i.e., let a and b be in Top (as mentioned in Sec. B, it is enough to assume that a and b are in Base). To prove $a + b \simeq b + a$, we have to prove $a + b \preceq b + a$ and $b + a \preceq a + b$. [convergence] says that to prove $a + b \preceq b + a$, we can assume that $a + b$ either has a value or raises an exception. If $a + b$ has a value, we conclude as before, i.e., we use one of our rules that says that if $a + b$ has a value then a and b are integers. Now let's assume that $a + b$ raises an exception e. Given our computation system, we can derive that either (1) a raises e, or (2) a computes to an integer and b raises e. We now need a rule to that effect:

$$\begin{array}{l} H \vdash \downarrow C \\ \quad \text{BY [AddExceptionCases]} \\ \quad H \vdash \texttt{isexc}(a + b) \\ \quad H, x : \texttt{isexc}(a) \vdash C\ \lfloor \textbf{ext}\ e_1 \rfloor \\ \quad H, x : a \in \mathbb{Z}, y : \texttt{isexc}(b) \vdash C\ \lfloor \textbf{ext}\ e_2 \rfloor \\ \quad H \vdash a \in \texttt{Base} \\ \quad H \vdash b \in \texttt{Base} \end{array}$$

Note that this rule does not say exactly what we wrote above. Using this rule, if $\texttt{isexc}(a + b)$ we only get to assume that $\texttt{isexc}(a)$ in our second subgoal, and not that $a + b$ and a compute to the same exception. This can be recovered using the following rule:

$$\begin{array}{l} H \vdash C\ \lfloor \textbf{ext}\ c \rfloor \\ \quad \text{BY [ExceptionBisimulation]} \\ \quad H \vdash \texttt{exc}(n, d) \preceq t \\ \quad H, [u : \texttt{Base}], [v : \texttt{Base}], [x : t \simeq \texttt{exc}(u, v)] \vdash C\ \lfloor \textbf{ext}\ c \rfloor \\ \quad H, u : \texttt{Base}, v : \texttt{Base} \vdash t \in \texttt{Base} \end{array}$$

Using this rule we can derive that if $\texttt{isexc}(a)$ then there exists some u and v such that $a \simeq \texttt{exc}(u, v)$. We are trying to prove that $a + b \preceq b + a$. Therefore, it is enough to prove $\texttt{exc}(u, v) + b \preceq b + \texttt{exc}(u, v)$. By computation we get that it is enough to prove $\texttt{exc}(u, v) \preceq b + \texttt{exc}(u, v)$. Now if b was to diverge, or raise an exception e different from (not computationally equivalent to) $\texttt{exc}(u, v)$, or compute to a value that is not an integer then $b + \texttt{exc}(u, v)$ would diverge, raise e, and get stuck, respectively. In all these three cases, we would not be able to prove $\texttt{exc}(u, v) \preceq b + \texttt{exc}(u, v)$. However, we can prove this result assuming that $b \in \mathbb{Z}$. Similarly, if $a \in \mathbb{Z}$ and $\texttt{isexc}(b)$ (third subgoal of [AddExceptionCases]) then we can conclude that $a + b \preceq b + a$.

Let us now discuss two peculiarities [AddExceptionCases], namely: (1) we have to prove that a and b are in Base, and (2) our conclusion C is squashed. Regarding (1), $a \in \texttt{Base}$ and $b \in \texttt{Base}$ are used to prove that the hypotheses introduced in [AddExceptionCases]'s second and third subgoals are well-formed propositions over the hypotheses H. Regarding (2), because we have squashed our conclusion C, it means that the extract of the sequent is $\star$. If the conclusion was not squashed, what could be the extract? We prove this rule in Nuprl's meta-theory by analyzing the expression $\texttt{isexc}(a + b)$. As mentioned above, we can derive that $a + b$ raises an exception e, and therefore that either a raises e, or a computes to an integer and b raises e. In the first case, we use [AddExceptionCases]'s second subgoal to prove that our conclusion is true, and in the second case we use [AddExceptionCases]'s third subgoal to prove that our conclusion is true. Therefore, if we could provide an extract for our sequent, it would be a term of the form if a is an exception then e_1 else e_2. However, to do that we would have to be able to catch all exceptions, which our computation system does not allow.

We have similar "exception cases" rules for the other non-canonical operator of our computation system.

As for [AddExceptionCases], to use [ExceptionBisimulation] we have to prove that $t \in \texttt{Base}$, which is enough to prove that the hypothesis $t \simeq \texttt{exc}(u, v)$ is a well-formed proposition. In [ExceptionBisimulation]'s second subgoal, the hypothesis u, and v are hidden to ensure that u and v do not occur in the extract c. If they were not hidden, and because u and v do not occur in our [ExceptionBisimulation]'s main subgoal $H \vdash C\ \lfloor \textbf{ext}\ c \rfloor$, instead of c, we would have to come up with a term that given t, computes t to an exception $\texttt{exc}(a, b)$ and extract the name a and the data b from that exception, and finally replace u by a and v by b in c. However, to do that we would need to be able to take apart any exception, which would mean that we would be able to catch any exception, which is not allowed by our computation system.

Here are a few more rules that we have proved regarding exceptions:

$$H \vdash C$$
BY [ExceptionConverges]
$H \vdash \mathtt{exc}(n,d) \preceq \bot$

$$H \vdash C$$
BY [ExceptionNotValue]
$H \vdash \star \preceq \mathtt{exc}(n,d)$

$$H \vdash a + \mathtt{exc}(n,d) \simeq \mathtt{exc}(n,d)$$
BY [AddException]
$H \vdash a \in \mathbb{Z}$

D. On the Extensionality of $\boldsymbol{\nu}$

In Sec. 4.2, we mentioned that to prove that $\sim$ is a congruence, it suffices to prove that the non-canonical operators of Nuprl are *extensional*.

An operator θ is extensional if for all $k \in \mathbb{N}$, and closed v (a value), $\overline{b}$ and $\overline{b'}$, if $\theta(\overline{b}) \mapsto^{k+1} v$ and $\overline{b} \preccurlyeq^* \overline{b'}$ then $v \preccurlyeq^* \theta(\overline{b'})$. We also get to use the following induction hypothesis IH: if for all closed t_1, t_2, t_3, if $t_1 \mapsto^k t_2$ and $t_1 \preccurlyeq^* t_3$ then $t_2 \preccurlyeq^* t_3$.

Let us motivate the changes we made to $\preccurlyeq^*$ by sketching the proof that $\boldsymbol{\nu}$ is extensional: we have to prove that if $\boldsymbol{\nu}x.t \mapsto^{k+1} u$ (where u is canonical, i.e., either a value or an exception), and $x.t \preccurlyeq^* x'.t'$ then $u \preccurlyeq^* \boldsymbol{\nu}x'.t'$ (we also get to use IH). Because $\boldsymbol{\nu}x.t$ reduces to a canonical form, this means that $t[x\backslash \boldsymbol{a}]$ reduces to either a value or an exception, for some "fresh enough" $\boldsymbol{a}$. If it reduces to a value z then $u = \Downarrow_x (z[\boldsymbol{a}\backslash x])$. Using IH, we get that $z \preccurlyeq^* t'[x'\backslash \boldsymbol{a}]$. Using Howe's Lemma 2 we get that $t'[x'\backslash \boldsymbol{a}]$ computes to a value w with same operator as z. We get that $z \preccurlyeq^* w$, where z is α-equal to some $z'[x\backslash \boldsymbol{a}]$ where $\boldsymbol{a}$ does not occur in z' and w is α-equal to some $w'[x\backslash \boldsymbol{a}]$ where $\boldsymbol{a}$ does not occur in w'. Therefore $z'[x\backslash \boldsymbol{a}] \preccurlyeq^* w'[x\backslash \boldsymbol{a}]$. It then remains to prove that $\Downarrow_x z' \preccurlyeq^* \Downarrow_x w'$. For example if $z' = \langle t_1, t_2\rangle$ and $w' = \langle u_1, u_2\rangle$, we have to prove that $\langle \boldsymbol{\nu}x.t_1, \boldsymbol{\nu}x.t_2\rangle \preccurlyeq^* \langle \boldsymbol{\nu}x.u_1, \boldsymbol{\nu}x.u_2\rangle$ which means that we have to prove that $\boldsymbol{\nu}x.t_1 \preccurlyeq^* \boldsymbol{\nu}x.u_1$ just knowing that $t_1[x\backslash \boldsymbol{a}] \preccurlyeq^* u_1[x\backslash \boldsymbol{a}]$. However, with the current definition of $\preccurlyeq^*$, we would have to prove that $t_1[x\backslash r] \preccurlyeq^* u_1[x\backslash r]$ for all closed term r.

E. Regarding the Operational Semantics of $\boldsymbol{\nu}$

In Sec. 4.1.2 we saw that we cannot reduce $\boldsymbol{\nu}x.\langle 1, x\rangle$ to $\langle 1, x\rangle$ because x would become free. Could we replace x with some default value such as, say, $\star$ or $\bot$? The problem with that is that any of these choices would break the properties of Howe's computational equivalence [54]. Say we pick $\star$ to replace v. Then we can prove that

$$\mathtt{if}\ \boldsymbol{a}{=}\boldsymbol{b}\ \mathtt{then}\ \mathtt{inl}(0)\ \mathtt{else}\ \mathtt{inl}(1) \preccurlyeq \mathtt{inl}(\mathtt{if}\ \boldsymbol{a}{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1)$$

where $\boldsymbol{a}$ and $\boldsymbol{b}$ are two different names. Therefore, we expect to be able to prove using congruence that

$$\boldsymbol{\nu}x.(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ \mathtt{inl}(0)\ \mathtt{else}\ \mathtt{inl}(1)) \preccurlyeq \boldsymbol{\nu}x.(\mathtt{inl}(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1))$$

However, because

$$\boldsymbol{\nu}x.(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ \mathtt{inl}(0)\ \mathtt{else}\ \mathtt{inl}(1)) \mapsto^* \mathtt{inl}(0)$$
$$\boldsymbol{\nu}x.(\mathtt{inl}(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1)) \mapsto^* \mathtt{inl}(\mathtt{if}\ \star{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1)$$
$$\mathtt{inl}(0) \not\preccurlyeq \mathtt{inl}(\mathtt{if}\ \star{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1)$$

then we would also get that

$$\boldsymbol{\nu}x.(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ \mathtt{inl}(0)\ \mathtt{else}\ \mathtt{inl}(1)) \not\preccurlyeq \boldsymbol{\nu}x.(\mathtt{inl}(\mathtt{if}\ x{=}\boldsymbol{b}\ \mathtt{then}\ 0\ \mathtt{else}\ 1))$$

Similar examples can be constructed for different default values. For example, for $\bot$, we can use $\mathtt{let}\ z := x\ \mathtt{in}\ \mathtt{inl}(0)$ and $\mathtt{inl}(\mathtt{let}\ z := x\ \mathtt{in}\ 0)$.

F. Squashing Inference Rules

Let us now present a few derivable inference rules to reason about our two main squash operators $\downarrow$ and $\lfloor$. Because most of them are trivial, we have proved them to be valid w.r.t. Allen's PER semantics (see Sec. A) directly in Coq: https://github.com/vrahli/NuprlInCoq/blob/master/rules/rules_squash.v.

First, let us present the rules about our $\downarrow$ operator as they are simpler:

$$H \vdash x = y \in \downarrow T$$
BY [SquashEqual]
$H \vdash T$
$H \vdash x \simeq \star$
$H \vdash y \simeq \star$

$$H \vdash \downarrow T$$
BY [Squash]
$H \vdash T$

$$H, x : \downarrow T, J \vdash C$$
BY [SquashElim]
$H, x : \downarrow T, J, [y : T] \vdash C$

$$H \vdash x \simeq \star$$
BY [SquashMember]
$H \vdash x \in \downarrow T$

[SquashEqual] says that to prove that x and y are equal members in $\downarrow T$, it's enough to prove that T is true and that x and y both compute to $\star$. [Squash] says that to prove $\downarrow T$ it is enough to prove T. [SquashMember] says that $\star$ is the only inhabitant of $\downarrow T$. The only non-trivial rule is [SquashElim] which introduces a hidden hypothesis. (Note that because y does not occur in $H, x : \downarrow T, J$ then it cannot occur in C either.) Therefore, we get to assume that T is true, but we do not get to know what term it is inhabited by. As mentioned above in Sec. A, hidden hypotheses can be unhidden when proving conclusions that do not have any computational content such as equalities. Using these rules we can derive the following elimination rule:

$$H, x : \downarrow T, J \vdash a = b \in C$$
BY [SquashElim]′
$H, x : T, J[x\backslash\star] \vdash a[x\backslash\star] = b[x\backslash\star] \in C[x\backslash\star]$

We now present the rules about our $\lfloor$ operator:

$$H \vdash x = y \in \lfloor T$$
BY [TruncationEqual]
$H \vdash x \in T$
$H \vdash y \in T$

$$H \vdash \lfloor T$$
BY [Truncation]
$H \vdash T$

$$H, x : \lfloor T, J \vdash a = b \in C$$
BY [TruncationElim]
$H, x : T, J, y : T \vdash a = b[x\backslash y] \in C$
$H, x : \lfloor T, J \vdash C \in \mathtt{Type}$
$H \vdash T \in \mathtt{Type}$

Rule [TruncationEqual] is similar to rule [SquashEqual], and rule [Truncation] is similar to rule [Squash]. Again, the only non-trivial rule is [TruncationElim]. The third subgoal

$$H \vdash T \in \mathtt{Type}$$

is necessary because $\lfloor$-types are extensional, i.e., $\lfloor T$ is equal to $\lfloor U$ if and only if T and U are types and these two types have the same

inhabitants. The second subgoal

$$H, x : \downarrow T, J \vdash C \in \texttt{Type}$$

is necessary to prove that C is functional w.r.t. the list of hypotheses $H, x : \downarrow T, J$. With the first subgoal we only get that C is functional w.r.t. the list of hypotheses $H, x : T, J, y : T$. Intuitively, the first subgoal tells us that $C[x\backslash u]$ and $C[x\backslash v]$ are equal whenever u and v are equal in T, when what we want to prove is that $C[x\backslash u]$ and $C[x\backslash v]$ are equal whenever u and v are both (not necessarily equal) members of T. Finally, the first subgoal

$$H, x : T, J, y : T \vdash a = b[x\backslash y] \in C$$

says that we get to unsquash x's type because we are proving an equality and because equality types do not have computational content. In addition, we also have to prove that our equality is functional w.r.t. the hypothesis $x : \downarrow T$, i.e., given another element y in T not necessarily equal to x, we have to prove that a is equal to $b[x\backslash y]$ in C.

G. Status of the Law of Excluded Middle

↓-Squashed law of excluded middle. As explained in [9], following Crary [37] as well as Kopylov and Nogin [60], we have proved [10, Sec. 5.2] that the following weak version of the law of excluded middle (LEM) is consistent with Nuprl:

$$\forall P : \mathbb{U}_i.\ \downarrow(P + \neg P)$$

where $\neg P$ is defined as $P \rightarrow \texttt{Void}$. Because the computational content of the disjoint union is erased (using the squashing operator $\downarrow$), one cannot use this to construct a magical decider of all propositions.

Anand's proof of ¬LEM. We can also prove directly in Nuprl the negation of LEM:

$$\neg\forall P : \mathbb{U}_i.\ P + \neg P$$

The simplest proof we know of is due to Abhishek Anand. Let us repeat it here. First let us prove that we cannot decide the halting problem:

$$\neg\forall t : \texttt{Base}.\ \texttt{halts}(t) + \neg\texttt{halts}(t) \tag{10}$$

From 10, it then follows trivially that the unsquashed LEM is false. Let us prove 10. Assume $\forall t : \texttt{Base}.\ \texttt{halts}(t) + \neg\texttt{halts}(t)$. Let us call that function *magic*. Using congruence, and because $\bot \preccurlyeq \star$, we can prove:

$$\begin{array}{l}(\lambda x.\texttt{if}\ (\textit{magic}\ x)\ \texttt{then}\ \bot\ \texttt{else}\ \star)\ \bot\\ \preceq(\lambda x.\texttt{if}\ (\textit{magic}\ x)\ \texttt{then}\ \bot\ \texttt{else}\ \star)\ \star\end{array}$$

Therefore, by computation, we get

$$\texttt{if}\ (\textit{magic}\ \bot)\ \texttt{then}\ \bot\ \texttt{else}\ \star \preceq \texttt{if}\ (\textit{magic}\ \star)\ \texttt{then}\ \bot\ \texttt{else}\ \star \tag{11}$$

The term $(\textit{magic}\ \bot)$ has type $\texttt{halts}(\bot) + \neg\texttt{halts}(\bot)$. Because $\bot$ diverges, we get that $(\textit{magic}\ \bot)$ is a right injection. Similarly, the term $(\textit{magic}\ \star)$ has type $\texttt{halts}(\star) + \neg\texttt{halts}(\star)$. Because $\star$ converges, we get that $(\textit{magic}\ \star)$ is a left injection. Therefore, from the approximation 11, we get $\star \preceq \bot$, which we can prove to be false. This concludes our proof of 10.

↓-Squashed law of excluded middle. Similarly we can prove the negation of the ↓-squashed LEM:

$$\neg\forall t : \texttt{Base}.\ \downarrow(\texttt{halts}(t) + \neg\texttt{halts}(t))$$

¬LEM from continuity. Using the weak continuity principle, following, e.g., Veldman's proof [95], we can proof that we cannot decide whether a sequence of natural number is equal to $\lambda x.0$ or not:

$$\neg\forall s : \mathcal{B}.\ s =_{\mathcal{B}} \lambda x.0 + \neg(s =_{\mathcal{B}} \lambda x.0) \tag{12}$$

Again, from 12 it then follows trivially that the unsquashed LEM is false. Let us repeat the proof of 12 here. Assume $\forall s : \mathcal{B}.\ s =_{\mathcal{B}} \lambda x.0 + \neg(s =_{\mathcal{B}} \lambda x.0)$. Let us call that function *magic*. We instantiate $\texttt{WCP}_{\downarrow}$ using the following function F in $\mathcal{B} \rightarrow \mathbb{N}$: $\lambda s.\texttt{if}\ (\textit{magic}\ s)\ \texttt{then}\ 0\ \texttt{else}\ 1$ and the following function f in $\mathcal{B}$: $\lambda x.0$. We get $\downarrow\mathbf{\Sigma} n{:}\mathbb{N}.\ \mathbf{\Pi} g{:}\mathcal{B}.f =_{\mathbb{N}^{\mathbb{N}_n}} g \rightarrow F(f) =_{\mathbb{N}} F(g)$. Because we are now proving `False`, we can unsquash this hypothesis and we get a n, which the modulus of continuity of F at f, as well as a function of type $\mathbf{\Pi} g{:}\mathcal{B}.f =_{\mathbb{N}^{\mathbb{N}_n}} g \rightarrow F(f) =_{\mathbb{N}} F(g)$. Let us now instantiate this formula using the following function g of type $\mathcal{B}$: $\lambda x.\texttt{if}\ x{<}n\ \texttt{then}\ 0\ \texttt{else}\ 1$. Because f and g agree upto n, we get: $F(f) =_{\mathbb{N}} F(g)$, i.e.:

$$\begin{array}{l}\texttt{if}\ (\textit{magic}\ f)\ \texttt{then}\ 0\ \texttt{else}\ 1\\ =_{\mathbb{N}}\ \texttt{if}\ (\textit{magic}\ g)\ \texttt{then}\ 0\ \texttt{else}\ 1\end{array} \tag{13}$$

Because $f =_{\mathcal{B}} \lambda x.0$, we get that $(\textit{magic}\ f)$ is a left injection, and because $g =_{\mathcal{B}} \lambda x.0$ is not true (starting from n the two sequences differ), we get that $(\textit{magic}\ g)$ is a right injection. Therefore, from the equality 13, we obtain $0 =_{\mathbb{N}} 1$, which is false and this concludes our proof of 12.

H. Relational Continuity Principle

Brouwer's continuity principle is often stated using a relational form such as in [40, 58, 92]. In that form one does not assume the existence of a function of type $\mathcal{B} \rightarrow \mathbb{N}$ but one assume that there exits a predicate P of type $\mathcal{B} \rightarrow \mathbb{N} \rightarrow \mathbb{P}$ such that for all f in $\mathcal{B}$, there exists a n in $\mathbb{N}$ such that $P\ f\ n$. If the existential is interpreted as being $\mathbf{\Sigma}$ then we can trivially obtain a function F of type $\mathcal{B} \rightarrow \mathbb{N}$ such that for all f in $\mathcal{B}$, $P\ f\ (F\ f)$. Also, given the fact that the ↓-squashed version of $\text{AC}_{1,0}$ is true in Nuprl, as explained in Sec. 5.3, we can also deduce $\downarrow\mathbf{\Sigma} F{:}\mathcal{B} \rightarrow \mathbb{N}.\ P\ f\ (F\ f)$. Because in the above formula the $\mathbf{\Sigma}$ is ↓-squashed, we can deduce the following variant of $\texttt{SCP}_{\downarrow}$:

$$\begin{array}{l}\mathbf{\Pi} P{:}\mathcal{B} \rightarrow \mathbb{N} \rightarrow \mathbb{P}.\\ \quad(\mathbf{\Pi} f{:}\mathcal{B}.\downarrow\mathbf{\Sigma} n{:}\mathbb{N}.\ P\ f\ n)\\ \quad\Rightarrow\ \downarrow\mathbf{\Sigma} M{:}(\mathbf{\Pi} n{:}\mathbb{N}.\mathbb{N}^{\mathbb{N}_n} \rightarrow (\mathbb{N}{+}\texttt{Unit})).\\ \qquad\mathbf{\Pi} f{:}\mathcal{B}.\\ \qquad\quad\mathbf{\Sigma} n, k{:}\mathbb{N}.\\ \qquad\qquad M\ n\ f =_{\mathbb{N}+\texttt{Unit}} \texttt{inl}(k)\\ \qquad\qquad\wedge\ P\ f\ k\\ \qquad\qquad\wedge\ \mathbf{\Pi} m{:}\mathbb{N}.\texttt{isl}(M\ m\ f) \rightarrow m =_{\mathbb{N}} n\end{array}$$
